(57) **ABSTRACT**

A notebook/laptop computer or other personal electronic device locking assembly includes a locking base secured to a working surface. The locking base locks the notebook computer or other personal electronic device securely in place to a work surface such as a desk top or table top. The lock is adapted to engage the notebook computer or other personal electronic device screen in the open position, leaving a front surface of the screen viewable. The lock includes a locking member which prevents removal of the notebook computer or other personal electronic device from the work surface.

PROTRUDING LOCK FOR NOTEBOOK COMPUTER OR OTHER PERSONAL ELECTRONIC DEVICE

RELATED APPLICATIONS

This application is a continuation-in-part of application Ser. No. 11/454,433 filed Jun. 15, 2006, now U.S. Pat. No. 7,443,665 which is a continuation-in-part of application Ser. No. 11/359,871, filed Feb. 22, 2006 now U.S. Pat. No. 7,324,333, and claims priority under 35 U.S.C. 120 therefrom, which application Ser. No. 11/359,871 claims benefit of provisional application Ser. No. 60/655,270 filed Feb. 22, 2005 and of provisional application No. 60/678,911 filed May 6, 2005, which application Ser. No. 11/359,871 is a continuation in part of application Ser. No. 11/038,591, filed Jan. 19, 2005 now U.S. Pat. No. 7,315,443 and claims priority under 35 U.S.C. 120 therefrom. application Ser. No. 11/038,591 claims benefit under 35 U.S.C. 119(e) from provisional application No. 60/569,561 filed May 10, 2004 and from provisional application No. 60/626,839 filed Nov. 10, 2004. This application also claims benefit under 35 U.S.C. 119(e) from provisional application No. 60/691,476 filed Jun. 17, 2005, from provisional application No. 60/725,333 filed Oct. 11, 2005, from provisional application No. 60/757,737 filed Jan. 10, 2006, and from provisional application No. 60/783,188 filed Mar. 16, 2006.

FIELD OF THE INVENTION

The present invention relates to security locks for laptop and/or notebook computers and other hand-held electronic devices, such as cell phones, personal digital assistants, personal music players (i.e. iPod®) and the like.

BACKGROUND OF THE INVENTION

Notebook computer or other personal electronic devices are increasingly used by students at educational institutions. They are also used by workers at job sites. Notebook computers are often referred to as laptop computers, meaning a portable, foldable computer which can be used while positioned upon the user's lap. In some instances, "laptop computer" refers to the term used in the trade for an older version of a larger portable computer. However, with increasing streamlining and downsizing of portable computers, compact, smaller versions are referred to as "notebook computers", but the terms are generally interchangeable.

In order to safeguard the personal electronic device, such as a notebook computer, it must be shut down, closed and transported by the user.

However, it is often advantageous for the user of a notebook computer to take a break and leave the computer open and operable at a work station or library study carrel, with other papers and books left at their current open position. This leaves the personal electronic device, such as a notebook computer vulnerable to theft.

Moreover, in the commercial retail environment, it is advantageous to display consumer electronic devices, such as notebook computers, cell phones or personal digital assistants in a secure but visually accessible display.

OBJECTS OF THE INVENTION

It is therefore an object of the present invention to provide a security lock for a personal electronic device, such as a notebook computer in an open position.

2

It is also an object of the present invention to provide a commercial retail display which allows visual access to notebook computers, cell phones and personal digital assistants while safeguarding these devices from shoplifting theft.

Other objects which become apparent from the following description of the present invention.

SUMMARY OF THE INVENTION

In keeping with these objects and others which may become apparent, the present invention is a desk surface locking base which holds a notebook and/or laptop computer, or a personal electronic device such as cell phones, personal digital assistants, personal music players (i.e. iPod®) in a secure but open position. When locked in place, the notebook computer or other personal electronic device is secure from being taken away from the surface to which it is locked. Furthermore, taking advantage of software and/or software/biometric security systems, the computer or other personal electronic device will also be unusable by unauthorized individuals when its owner is away from the area for a break, telephone call, or other short-term pursuits. With a few keystrokes, the owner of the computer or other personal electronic device can resume activity in exactly the same place as when activity had been suspended. This is especially useful for leaving an active computer or other personal electronic device on a study desk or library carrel.

In one embodiment, the notebook computer or other personal electronic device lock includes a locking base having a receptacle for receiving a distal end of a pivotable locking member pivotably attached at a proximal end thereof to the locking base. The locking member locks the computer screen between it and the locking base. The locking base is fastenable to a notebook computer work surface, such as a desk top or other table surface, in the vicinity of the notebook computer. A pin lock secures the locking bar across the display screen portion of the notebook computer or other personal electronic device and into a hole in the locking base, thereby securing the notebook computer or other personal electronic device in a locked position within the components of the notebook computer or other personal electronic device lock.

In another embodiment, the locking base is screwed or otherwise fastened to the work surface in a permanent fashion. A locking collar is then removed from the base and then placed over the liquid crystal display (LCD) screen of the open notebook computer or other personal electronic device within the framework of the locking base. A lock, such as a padlock, is then used to lock together the locking collar and the locking base, thereby making it impossible to remove the notebook computer or other personal electronic device from the work surface.

In this embodiment, the notebook computer or other personal electronic device locking assembly includes a locking base for being secured to a working surface, wherein the locking base has a rear wall to receive a keyboard portion of the notebook computer or other personal electronic device with a screen portion of the notebook computer or other personal electronic device in the open position resting parallel to the rear wall. The rear wall has a rearwardly extending locking flange along a top edge of the rear wall. A locking frame includes a second rear wall having side walls and a locking bar joining the side walls, wherein the locking frame is adapted to slide over the screen portion of the notebook computer or other personal electronic device in the open position, with the second rear wall between the screen portion and the first rear wall and the locking bar extends across a front surface of the screen portion.

3

This second rear wall has a rearwardly extending locking flange along a top edge of the second rear wall on top of, and flush against, the locking flange of the first rear wall. The side walls of the locking base have tabs bent toward the computer or other personal electronic device, with the locking bar falling behind the bent tabs, when the locking frame is deployed on the notebook computer or other personal electronic device, thereby preventing removal of the notebook computer or other personal electronic device from the locking base. Additionally, locking holes in both flanges are aligned with each other to receive a padlock to lock the locking frame to the locking base.

Fasteners are employed to attach the locking base to the working surface, so that the fasteners are kept under the keyboard portion of the computer or other personal electronic device.

The lower edges of the rear walls are raised a sufficient distance to allow access to connectors on a rear surface of the keyboard portion of the computer or other personal electronic device.

Preferably, an optional cage is attached to a rear of the first rear wall to house an auxiliary battery, charger or battery eliminator.

In an alternate embodiment, an elongated framework of the locking base is used that supports the LCD screen of the notebook computer at the proper viewing angle, just as in the preferred embodiment. In this case, however, the locking device is a transparent screen cover, such as of LEXAN® polycarbonate, which is placed over the screen and then locked to the locking base with a lock, such as a padlock. This panel is also a screen protector. This is a desirable feature for a demo station at a retail outlet, to display and demonstrate a notebook computer or advertise another product. Using an auxiliary locking flange, this embodiment is also compatible with the locking collar of the preferred embodiment. This use mode does not obscure viewing of the LCD screen directly, when viewing the display screen through the transparent polycarbonate sheet. Similar smaller locking bases with polycarbonate or other strong locking panels can be used to display and demonstrate consumer devices, such as personal digital assistants (PDA's), scientific calculators, and cell phones, on store shelves.

This embodiment may also have an optional accessory cage made of heavy wire mesh or perforated metal, which can be attached to the back portion of the locking base. This securely contains a battery charger/eliminator for the notebook computer.

In this embodiment with a transparent screen cover, the notebook computer or other personal electronic device locking assembly includes a locking base secured to a working surface, with the locking base having a pair of side walls and a rear wall to receive a keyboard portion of the notebook computer or other personal electronic device, wherein a screen portion of the notebook computer or other personal electronic device is oriented in the open position, resting adjacent to the rear wall. This rear wall has a rearwardly extending locking flange along a top edge thereof.

The transparent locking frame has a surface adapted to rest adjacent to, or against, a front surface of the screen. A top wall is adapted to rest against a top surface of the screen portion of the computer or other personal electronic device, with a rear wall extending down from the top wall, adjacent to a rear surface of the screen portion of the notebook computer or other personal electronic device. A rearwardly extends flange from a bottom edge of the rear wall, with the rearwardly extending flange positioned adjacent to the rearwardly extending locking flange of the locking base.

4

In this embodiment, locking holes in both flanges are aligned with each other to receive a padlock, to lock the transparent locking frame to the locking base.

In this embodiment, an optional shelf or shelves may be provided to display handheld electronic accessories, such as cell phones, PDA's, calculators, video game controls, etc., for retail viewing purposes through the transparent screen cover.

In yet another embodiment, the pivoting locking rod, locking collar or transparent polycarbonate locking panel is replaced by a telescoping rod, a vinyl covered steel cable, or a flexible tubing covered chain. Like the pivoting rod version, this embodiment therefore eliminates the removable portion of the locking base system (such as the locking collar or transparent polycarbonate panel), and instead uses a locking device that is permanently attached to one side of the locking base itself. This locking device is also locked with a padlock by first passing the distal end of the locking member through a hole in the opposite side panel member of the locking base thereby preventing removal of the notebook computer or other personal electronic device.

In this embodiment, the notebook computer or other personal electronic device locking assembly includes a locking base secured to a working surface, with the locking base having a pair of side walls and a rear wall to receive a keyboard portion of the notebook computer or other personal electronic device. A screen portion of the notebook computer or other personal electronic device is held in the open position, resting against and/or parallel to the rear wall, with the side walls extending past a front surface of the screen portion. A telescoping locking bar or flexible locking cable is hinged at one end to one of the side walls, in front of the screen portion. An opposite end of this telescopic or flexible locking bar or cable has a plug with an opening therethrough. An opening in the other of the side walls is configured to align with the opening in the plug, when the locking bar is rotated across a front surface of the screen portion, with the plug positioned adjacent the other of the side walls to accommodate a padlock, to lock the notebook computer or other personal electronic device into the locking base.

In a further embodiment the computer lock or electronic device lock is attached to a horizontal desk or work surface via a locking base which is separate from the computer lock itself. The computer lock is then slipped into the locking base from the side and both the computer and locking base are then secured to the work surface. In this manner, no holes are drilled into the work surface, and the locking base is removable yet secure. The locking base is secured to the work surface by a clamp which goes over the front edge and engages the bottom surface via a screw with a pointed end which is tightened so as to indent the underside and thereby attach. The screw itself can have a security head such as an allen socket with a concentric protruding rod which prevents the use of a simple allen wrench. A specialty security allen wrench with a hole to accommodate the protruding rod is required for the initial attachment as well as subsequent removal. A side bracket attached to the clamp also accommodates a mailbox type key lock which can be used to deny access to the attachment screw head for an extra measure of security. If the key lock is used, an ordinary non-security screw can be used since the lock tang itself will adequately secure the screw. The computer lock used with this embodiment has a horizontal frame member with two vertical side brackets at each end attached to base plates which can be screwed to a work surface as in the previous embodiments or used with the locking base.

A bar which is captively attached to one bracket secures the bottom of the notebook computer display when the other end

5

is passed through a hole in the distal bracket and a key lock is then slipped over the bar end which has a groove compatible with the lock.

In an alternate embodiment wherein a clamp wraps around a work surface to lock the notebook computer or other personal electronic device in place, the clamp itself may be the locking base itself, connected to the personal electronic device by a cable or other locking connection.

In another embodiment, the above noted computer lock or electronic device lock is attached to directly to a horizontal desk or work surface by fasteners.

Yet another embodiment of a computer lock, the lock has a continuously width adjustable feature to accommodate computers with a variety of display width sizes. It includes a left portion with vertical bracket, base attachment plate, horizontal member, and captive lock bar. A right portion has a vertical bracket, base plate and hollow horizontal member sized to receive the left horizontal member in a telescoping fashion. The locking bar is fabricated of a left portion which is a threaded tubing member having coarse threads. The right portion of the locking bar is a solid member with mating external threads on its long end. This computer lock is used with the locking base of the previous embodiment to take advantage of its telescoping feature. (It can also be screwed down to a work surface directly, but the adjustable feature would be defeated unless screws are moved to other adjustment holes.)

To use the computer lock, the user places a notebook computer within the side brackets, and then pushes the sides in adjacent to the computer display. Then the user screws the distal end of the locking bar in or out to facilitate the end fitting through the lock holes on the right bracket. When locked with a key lock, the bar will secure the computer and prevent the spreading of the side brackets.

In a related embodiment, the width adjustable feature is discrete instead of continuous. Although any suitable width adjustment mechanism can be used, a suggested type uses a peg which fits into a hole in the larger of the two telescoping members. The inner telescoping member has a series of holes which define the width steps when in registration with the single hole of the larger/outer telescoping member. The peg locks the outer hole to one of the inner holes.

In another embodiment, the locking base described above is integrated with a computer lock or electronic device lock in a single unit. Thus the computer or other personal electronic device lock is now directly attached to the work surface via a clamp that goes over an edge of a work table and locks into the bottom surface of the work table.

In yet a related embodiment, the integrated locking base/computer or other personal electronic device lock has two pivots from the clamp end to the computer or other personal electronic device lock so that much positional freedom is afforded the locked computer or other personal electronic device over the work surface. For example, this pivoting embodiment can be used on corners of work tables.

In a preferred embodiment for consumer use, a low profile locking base with a narrow footprint is used. Due to its smaller dimensions, less material is required. Since it can be stamped and formed from a single rectangular sheet with little waste, the process for manufacture is very efficient. Heavy gage aluminum sheet or stainless steel sheet can be used. It is therefore lighter and more economical.

In one application this locking base is permanently screwed down to the work surface, and the user would have his or her own pin lock, to secure the locking bar across the display portion and into the base back, thereby securing the notebook computer or other personal electronic device.

6

However, the preferred mode of use for this embodiment is to combine the locking base with a cable and clamp as a portable kit which fits into a convenient tubular carrying case. The clamp is attached to the work surface or to a table leg or any convenient non-movable structure in the vicinity.

This clamping of the clamp to a work surface is accomplished by tightening a clamp screw against the work surface, such as a table top or desk top. The clamp screw extends from a clearance hole in a container, such as a short tube, with a large axial hole at the distal end that accommodates the screw head. An appropriate tool compatible with the type of screw head used is entered from the distal hole to tighten or loosen the clamp while also capturing the short tube; this can be an allen wrench, a screwdriver, or a hex head driver as appropriate.

The cable has a small end ferrule with a transverse hole on one end and a ferrule with a larger end attached to the distal end of the cable. A transverse hole in the lower portion of the short tube accepts the ferrule and cable, but is sized to prevent access to the larger end of the distal ferrule.

In use, the clamp is attached to the structure, such as a desk top, as described; then the cable is threaded through the transverse hole in the short tube. The end of locking bar is passed through the cable ferrule with the transverse hole prior to locking it to the locking base. In this manner, although the computer or other personal electronic device can be moved around on the work surface, it is secured by the cable.

It is noted that the cable being threaded through the transverse hole in the container, such as the short tube, denies access to the clamp screw head. The cable must be removed before the clamp can be loosened from underneath of the desk top or other work surface.

In an alternate embodiment of the clamp screw subassembly of this preferred embodiment, no tool is required to tighten or loosen the clamp. For example, a hollow knob with a captive locking member, such as a clamp screw, emerging from a clearance hole in an end cap, is used.

The clamp screw has a tall head and can be a hex, square or other geometric configuration. A recess with a configuration matching the screw head is formed into the inside surface of the end cap such that a slight pull on the knob against the captive screw head (i.e.—away from the clamp) will seat the head into the recess with a slight turn. Thus the end cap is a socket wrench used to either tighten or loosen the clamp.

A strategically placed offset transverse hole is prevented from accepting the cable by the screw head if the screw head is seated in the wrench recess.

By pushing up on the end of the knob (toward the clamp), clearance for the cable to enter through the transverse hole adjacent to the screw and between the head and end cap is formed. Thus, the screw head is spaced apart from the end cap socket wrench recess as long as the cable is present. If the knob is turned while the cable is installed, it will just turn freely with no ability to loosen the clamp even if force away from the clamp is used. The cable must be removed before the clamp can be loosened.

In a further embodiment of this invention, a notebook computer or other personal electronic device is provided with a security hole through the hinge area between the display and the base, through the edge of the display, or diagonally through a corner of the base. A protruding spike or rod, with a head on one end and a transverse hole near the distal end, is used to secure the computer or other personal electronic device. The spike or rod is inserted through the security hole, and a ferrule on the end of a secure cable is then inserted

7

through the transverse hole of the spike or rod, and is locked by a pin lock compatible with the groove feature at its distal end.

In a variation of this embodiment, the spike or rod is replaced by a captive security rod with a transverse hole. In one design, this security rod is stored in a one end of the hinge in a direction co-linear with the hinge.

In an alternate design, the security rod can rise vertically from the computer base or base of the personal electronic device. A small knob is attached to grasp the rod which may be stored in the recess by a quarter-turn feature or by a magnetic force.

An alternate type of spike locking feature does not depend on the use of a secure cable; a longer separate spike is used. It is designed to penetrate through a hole in a convenient location in the computer base or personal electronic device base from the top, through the base thickness, and further through a pre-drilled hole in the table or desk top. This long spike has a transverse hole which emerges beneath the table top. A pin with a groove near its distal end is then inserted through the transverse hole of the long spike and locked by a pin lock.

In a further alternate embodiment, the protruding rod may take the form of a thin rigid or flexible strip. The strip may be inserted within a thin, longitudinally extending hole, such as a slot, within the body of the personal electronic device, such as a notebook computer.

On the other hand, if the notebook computer has a hinge between the display screen and the main body of the personal electronic device, such as in a hinged notebook computer, cellphone or personal digital assistant (PDA), then, if the strip is flexible, it can be inserted within the hinge gap between the display screen and main body of the device, such as a keyboard portion of a notebook computer.

The thin, flexible or rigid long rectangular strip includes a wedge stop at a proximal end and a distal end being thin enough to weave within the slot of a personal electronic device, or through the hinge gap of a hinged instrument such as the gap between display and keyboard of a notebook computer. If the rectangular strip is flexible, preferably, the thickness of this strip is between 0.004 inches and 0.064 inches. The composition of the flexible strip is flexible reinforced plastic or metal such as heat treated steel shim stock. Springy stainless steel shim type stock is also a useful material as well a variety of other steel alloys.

After the distal end of the locking strip is passed through the slot in the personal electronic device, or alternatively through the hinge gap in the device being secured, it is clamped by a strip-holding locking clamp, which itself is attached to the work surface, or is otherwise secured to it as by a secure cable. The strip-holding clamp may have locking jaws with serrations which aggressively grip the distal end of the locking strip when a key lock is closed by a matching key. The lock is similar to a mailbox lock with a tang that engages a lock recess in the lower base section of the locking clamp thereby overcoming a spring force which keeps the jaws apart slightly when not locked. The key is also used to unlock the two mating jaws to release the locking strip and thereby unsecure the device. In a library environment, both the key for a particular clamp as well as a locking strip can be borrowed from a librarian to secure the device in a locked state.

In an alternate embodiment of the locking clamp, the distal end of the locking strip is inserted in the clamp end through a slot formed by two upright members and a robust leaf spring attached to a pivoted handle. The handle is pressed down toward its distal end (thereby offering much mechanical advantage for the operation) bending the leaf spring thereby clamping the distal end of the locking strip in a slight recess

8

with transverse serrations in the clamp base. The shackle of an ordinary key or combination padlock is then passed through loops attached to the clamp base as well as a loop at the distal end of the handle (in registration) and locked. By locking the handle in a down position, the device is kept secure by frictional forces opposing pull-out arising from the normal spring force. In this manner, any person with an appropriate padlock and a locking strip can lock his own device to a work surface using any available clamp. The need to receive from and return to a librarian a specific key is eliminated.

In an alternate embodiment of the locking strip itself, whether it be flexible or rigid, a large hole is provided near the distal (free) end of the strip. This permits a variety of methods of locking the strip to the work surface in lieu of a clamp. In one method, a round stud with a transverse hole near its distal end is attached to the work surface in a perpendicular orientation (sticking up). The locking strip is inserted through the hinge gap in the device to be locked and then the hole in the locking strip is passed over the stud; the shackle, of an ordinary key or combination padlock is then passed through the transverse hole in the stud thereby locking the strip to the work surface. In a second method, a secure cable with a stud at its end is provided. The cable stud is passed through the hole in the locking strip, and then a cable lock that fits the stud is locked onto it thereby locking the strip to the secure cable. In a third method, a free cable with a stop member permanently attached at one end is passed through the hole in the locking strip. The cable is then looped or otherwise secured to (or adjacent to) the work surface.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention can best be understood in connection with the accompanying drawings. It is noted that the invention is not limited to the precise embodiments shown in drawings, in which:

FIG. 1 is a perspective view of a locking base and locking collar of one of the embodiments for a notebook computer lock of this invention;

FIG. 2 is a side view of the embodiment of FIG. 1, taken along in the direction of arrow "2" of FIG. 1, showing a typical notebook computer locked with a locking base and locking collar to a work surface with a padlock;

FIG. 2A is a partial fragmentary view of the locking base as in FIG. 2, taken along in the direction of arrow "2A" of FIG. 2;

FIG. 2B is a partial perspective view of the typical notebook computer locked in place between the locking base and locking collar of FIG. 2;

FIG. 2C is a partial front elevational view of the locking base and locking collar as in FIG. 2;

FIG. 2D is a side elevational view of the notebook computer shown used by a person at a work station;

FIG. 3 is a perspective view of an alternate embodiment showing a typical notebook computer in the locking base with an elongated back side;

FIG. 3A is an exploded perspective view of a further embodiment, showing handheld electronic accessories displayed upon respective shelves, added to the front side of the locking base of FIG. 3;

FIG. 3B is a close-up of one type of key lock used with the notebook computer lock of the present invention;

FIG. 4 is a side view of alternate embodiment for a notebook computer lock of FIG. 3, showing dual locking flanges;

FIG. 5 is a perspective view of a transparent locking panel of the alternate embodiment shown in FIG. 4;

9

FIG. 6 is a side edge view of the transparent locking panel showing a locking flange, taken along in the direction of arrow "6" of FIG. 5;

FIG. 7 is a top plan view of the transparent locking panel showing a padlock hole in the locking flange, taken along in the direction of arrow "7" of FIG. 6;

FIG. 8 is an exploded perspective view showing the addition of an optional battery pack housing cage feature to the locking apparatus of the embodiment shown in FIG. 1, although it can be used with any of the embodiments herein;

FIG. 9 is a side view of the locking apparatus of FIG. 8 used on a notebook computer showing the housing cage feature;

FIG. 10 is a perspective view of a further alternate swing arm embodiment using a swinging arm, such as a telescoping bar, to secure a typical notebook computer;

FIG. 11 is a top plan view of a clad steel cable used as a locking element for the further alternate swinging arm embodiment;

FIG. 12 is a top plan view of a chain inside a flexible tube as an alternate locking element in the embodiment of FIG. 10;

FIG. 13 is a perspective view of an alternate embodiment of a notebook computer lock using a separate "over the table" locking base and a computer lock using a captive swinging locking bar, which fits across lower portion of the display;

FIG. 13A is a front elevation of a clamp detail of the locking base shown in FIG. 13, taken along the ellipse 13A of FIG. 13;

FIG. 13B is a clamp bracket side elevational view thereof, showing use of a key lock;

FIG. 14 is a side edge view of the locking base of FIG. 13, shown attached to a work surface;

FIG. 15 is a top plan view of the computer lock of FIG. 13, secured within a locking base, also showing the position of the notebook computer with dashed lines;

FIG. 16 is a perspective view of one embodiment for a width adjustable notebook computer lock;

FIG. 17 is a perspective view of a further embodiment for a discrete width adjustable notebook computer lock;

FIG. 18 is a perspective view of an integrated locking base/computer lock embodiment;

FIG. 19 is a top plan view of another integrated locking base/computer lock with two pivot links;

FIG. 20 is a perspective view of a preferred embodiment for a low profile notebook computer, shown attached by fasteners, such as screws, down to the work surface;

FIG. 21 is a perspective view of the locking base of FIG. 20 used as a portable device secured to the work surface via a cable and clamp;

FIG. 22 is a detail side view of the clamp screw subassembly used in FIG. 21, shown in the ellipse "22" of FIG. 21;

FIG. 23 is an exploded perspective view of the components of an alternate embodiment with a socket wrench type clamp screw subassembly;

FIG. 24 is a bottom view of the end cap of the embodiment of FIG. 23, showing the recess which forms the socket wrench element;

FIG. 25 is a top view of the clamp screw assembly as in FIG. 23, shown with the captive screw;

FIG. 26 is a side view crosssection of the clamp screw assembly as in FIG. 23, taken along line "26-26" of FIG. 25, shown with the screw head seated in the socket wrench recess and preventing insertion of the cable;

FIG. 27 is a side view in crosssection of the clamp screw assembly as in FIG. 23, shown with the cable preventing seating of the screw head in the socket wrench recess.

10

FIG. 28 is a perspective view showing the possible locations of through-holes for use of an alternate protrusion spike embodiment security feature used with a cable;

FIG. 28A is a perspective detail showing the closed front section of a notebook computer wherein a security feature is two through holes which align upon closing display lid permitting a padlock with an elongated hasp to lock the display to the keyboard base.

FIG. 28B is a perspective view of a notebook computer with a security hole in the top right corner of the display section.

FIG. 28C is a perspective view of the computer of FIG. 28B with a pin lock and locking ferrule aligned prior to insertion through security hole.

FIG. 28D is a perspective view of the computer of FIG. 28C after pin lock is used to secure ferrule thereby using a cable to secure computer to a table top.

FIG. 29 is a perspective view of the spike with a cable attached ferrule, pin lock, and secure cable clamp used to secure a notebook computer;

FIG. 30 is a schematic perspective view of a notebook computer with captive security rods for cable attachment;

FIG. 31 is a schematic perspective view of a notebook computer with a hole downward through the base for use with a long protrusion spike and a transverse locking pin;

FIG. 32 is a diagrammatic side elevational view of one embodiment for a flexible strip lock for a computer;

FIG. 33 is a front elevational view thereof, taken in the view direction of arrow "33" shown in FIG. 32;

FIG. 34 is a top plan view of the shim strip of the flexible lock;

FIG. 35 is a side elevational view taken in the view direction of arrow "35" of FIG. 34;

FIG. 36 is a perspective view of a lower protective shoe of the flexible lock;

FIG. 37 is a diagrammatic perspective view illustrating a flexible locking means;

FIG. 38 is a diagrammatic exploded view of a key locking means with a spring;

FIG. 39 is a partial view of a key locking means;

FIG. 40 is a perspective view of a notebook computer showing the hinge gap and the path of weaving the distal end of a locking strip through the hinge gap, as well a slot in the housing of the notebook computer permitting access to a rigid protruding locking strip therein;

FIG. 41 is a perspective view of a "flip top" cellular phone showing the hinge gap;

FIG. 42 is a perspective view of a PDA showing the hinge gap;

FIG. 43 is a perspective view of a personal DVD player showing the hinge gap;

FIG. 44 is a side elevation of an alternative embodiment of a strip captivating locking clamp of this invention, shown using an ordinary padlock;

FIG. 45 is a top view of the base portion of FIG. 44;

FIG. 46 is a side elevation of the handle portion of the alternate embodiment clamp of FIG. 44;

FIG. 47 is a bottom view (in the direction of arrow "47" in FIG. 46) of the handle of FIG. 46;

FIG. 48 is a top plan view of a further alternate embodiment for a locking strip of this invention;

FIG. 49 is a perspective view of the locking strip of FIG. 48 secured to a stud attached to the work surface by the use of a padlock;

FIG. 50 is a perspective of an alternate method of securing the locking strip of FIG. 48 by the use of a secure cable and a cable lock; and,

11

FIG. 51 is a perspective view of yet another method of securing the locking strip of FIG. 48 by virtue of a free cable with attached stop member.

DETAILED DESCRIPTION OF THE INVENTION

FIG. 1 shows locking base 1 for a notebook computer lock, which is secured to a working surface by fastener holes, such as screw through holes 4 in base mounting pads 3. A back surface 10 is tilted at angle "X" to provide a good viewing angle of the computer screen. Side panel members 6 with bent tabs 7 provide a space for sliding locking collar 2. Locking flange 8 with a locking hole, such as padlock hole 9, is used to secure locking collar 2 with flange 14 via hole 15, which is in positional registration with hole 9 when mated. Width "W" is wider than the widest notebook computer or other personal electronic device to be accommodated by this locking base system. Locking bar 12, attached to the distal ends of sides 13, actually secures the notebook computer or other personal electronic device. This is the preferred embodiment. The display screen portion rests within space 16 between sides 13. In use, the keyboard portion of a notebook computer or other personal electronic device would deny access to the fasteners, such as retaining screws, in holes 4.

Side panel members 6 may have one or more ports 6a to accommodate computer cables therethrough.

FIGS. 2, 2A, 2B and 2C show how locking collar 2 is placed over notebook computer screen 19 and then upon flange 14, and is locked to lower flange 8 via a lock, such as padlock 20. Keyboard 18 fits between sides 6. Space 5 is created by a raised back panel 10 so as to permit access to a variety of connectors at the back of computer keyboard portion 18. FIG. 2 also shows an optional compartment 42 for a power source accessory 43, such as an auxiliary battery charger or battery eliminator, wherein compartment 42 extends between power flange 8 and further lower flange 8A.

FIG. 2D shows the notebook computer being used by a person at a work station;

In an alternate embodiment shown in FIG. 3, upright portion 25 supports the entire height of screen 19 above raised back panel 10 mounted upon base pads 3. This can also be shown in FIG. 4. FIG. 3B shows another example of a lock 20a, which can be used in lieu of padlock 20.

FIG. 3A shows a further alternate embodiment where shelves 36 and 36a are depicted supporting electronic hand-held devices such as folding cell phone 37a, upright cell phone 37b, marine VHF radio 37c, personal digital assistant 37d, calculator 37e and video game pad controller 37f.

A transparent panel, such as LEXAN® polycarbonate panel 30, shown in FIG. 5, is used as a locking frame, by sliding it over screen 19 within the four tabs shown in FIG. 3 at the distal corners of upright 25.

Panel 30, shown in FIGS. 4-7, has a top portion 32 and a locking flange 33 with padlock hole 35. In use, this hole is in positional registration with that of upper locking flange 27 shown in FIG. 4. A padlock 20 or other small lock 20a can be used to secure the two members together. Front face 31 of transparent panel 30 protects the surface of computer screen 19. This can be used to advantage in a retail demo environment. Alternately, the locking collar of FIG. 1 can be used with base of FIG. 3 by locking into lower locking tab 26; this would offer a better unencumbered view of screen 19.

FIG. 8 shows the addition of an optional battery pack housing cage 42 feature to the locking apparatus of the embodiment shown in FIG. 1, although it can be used with any of the embodiments herein;

12

The optional power source component 42 of FIGS. 2 and 8 can be added to any of the embodiments of this invention, including those shown in FIGS. 3-51. It is preferably a cage made of heavy duty wire screen or perforated metal that is attached (as by welding or rivets) to a rear panel, such as panel 41 in FIG. 8. This provides a secure compartment 42 for a power source accessory 43, such as an auxiliary battery, charger, or battery eliminator.

Compartment 42 is also shown in the side view of FIG. 9.

In a further alternate embodiment, shown in FIG. 10, a locking base using a telescoping rod 54 is shown. In this embodiment, there is no member such as locking collar 2 or transparent panel 30 that can be readily removed from the locking base when a computer or other personal electronic device is not secured to the base. This should reduce the incidence of vandalism or theft of the removable item which would render the base unusable. In FIG. 10, one end of bar 54 is attached to the left side panel member 51 of base 50 via a pivotable fastener, such as ball joint 53. After the notebook computer or other personal electronic device is inserted between sides 51 and 52, bar 54 is swung over the lower (hinge) portion of the notebook computer's screen, such as a liquid crystal display (LCD) screen and is elongated so as to insert lock plug 55 through locking hole 56 in right side 52. A lock (not shown), such as padlock 20, is then inserted through the hole in plug 55 thus locking computer to base.

Alternate locking members include locking members such as vinyl clad steel cable 60 shown in FIG. 11, and the flexible tubing clad chain 65 shown in FIG. 12. These two devices do not require a ball joint attachment to left flange 51. Cable 60 can be simply inserted through a hole in flange 51 and then retaining washer 61 can be permanently attached as by spot welding. Lock plug 55, used as for telescoping rod, is attached to the distal end of cable 60. Chain 65 can be attached to flange 51 in a similar fashion by attaching washer 66 to its proximal end after threading through a hole. The distal end of chain 65 has an elongated link 67 with stop washer attached. The padlock is engaged through this link after it emerges through hole 56 in side 52.

FIG. 13 shows an alternate embodiment using a separate locking base 81 used with a notebook computer or other personal electronic device lock 80 which slides in from the left so that one or more base pads 87 are retained by one or more brackets 82 on base 81. FIGS. 13 and 14 also show a clamp 86 which secures the lock in place by clamping the lock over a working surface, such as a table top 85.

A better view of this is the side edge view of FIG. 14. Clamp 86 slips over the edge of work surface 85. Locking bar 84 is captive in left bracket of computer or other personal electronic device lock 80, but it can swing out to permit access of computer or other personal electronic device display. The distal end 88 is grooved to accommodate a key lock to secure the computer or other personal electronic device as well as lock 80 to base 81. The long neck portion of base 81 from clamp 86 to brackets 82 positions the computer or other personal electronic device at a convenient distance from the front edge of table working surface 85. The detail of clamp 86 in FIG. 13A shows how screw 92 with optional security head 91 is screwed into the bottom surface of table working surface 85 via pointed end 93.

FIG. 13B shows how tang 97 prevents screw 91 from being loosened when lock 95 is locked via key 96. Lock 95 can be easily removed from hole 94 in lock bracket 90. When tang 97 is turned to position 98, screw head 91 is not obstructed so that it can be removed or tightened.

FIG. 15 is a top plan view showing details of notebook computer or other personal electronic device lock 80 locked

13

to base **81** with a computer or other personal electronic device display shown in dashed lines in position **117** and keyboard shown in dashed lines in position **118**. Power supply box **100** can pivot open in the direction of arrow **101** on shaft **102** with a retaining cap; it is locked via tang **112**. Notebook computer or other personal electronic device lock **80** is slid into a captive position within brackets **82** retaining the edges of base plates **87** in the direction of arrow **104**. The left end of swinging locking bar **84** (which can swing out in the direction of arrow **103**) is retained via retaining cap **105** within slotted hole **115** and an oversize hole on front of the left bracket. Key lock **110** grasps rod end **88** of swinging locking bar **84**, which maintains the security of the assemblage via bracket tang **114**, which is part of locking base **81**. Key **111** can be used to remove the lock body from the end of swinging locking bar **84**.

While FIG. **13-15** shows a separate over the table locking base **81** used with a notebook computer or other personal electronic device lock **80** which slides in from the left so that base pads **87** are retained by brackets **82** on base **81** of notebook computer or other personal electronic device lock **80**, it is contemplated that a further alternate embodiment includes attaching notebook computer or other personal electronic device lock **80** directly to a work surface **85**, such as a study desk, by providing fastener receptacles within base pads **87**, wherein fasteners, such as screws or bolts fasten base **81** directly to an upper side of the work surface **85**, without the use of over the table base **81**.

FIG. **16** shows another embodiment of a notebook computer or other personal electronic device lock **130** with a telescoping width adjusting feature to accommodate computer or other personal electronic devices of varying widths more securely. Base pads **136** are compatible with the use of locking base **81** of the previous embodiment to retain this continuous adjustment feature. Locking bar portions **137** and **138** are adjustable in size.

For example, as in FIG. **17**, incrementally spaced detents or pins and holes may be used to facilitate width adjustment.

Alternatively, as in FIG. **16**, locking bar **137** may be hollow and threaded with a coarse thread; it is captive within left bracket **134** and slotted back hole **133**. Right section of locking bar **138** is screwed into portion **137** and can be quickly length adjusted by twisting it clockwise or counter-clockwise. Horizontal section **131** fits into section **132** in a telescoping fashion. After the notebook or laptop computer or other personal electronic device display is placed between the spread-apart brackets, the brackets are pushed against its sides and swinging locking bar portions **137** and **138** are adjusted accordingly to fit into holes in right bracket **135** for locking.

FIG. **17** shows a different width adjustable computer or other personal electronic device lock **170** with a discrete locking mechanism including pivoted flange **178** with peg **176** at its distal end. Flange **178** is pivoted on pivot **182**, such as a rivet, attached to outer telescoping member **132** of notebook computer or other personal electronic device lock **170**. When swung in the direction of arrow **179**, flange **178** will force peg **176** through hole **175** in telescoping section **132** and further into one of the holes **180** in inner telescoping member **171** when in positional registration. Flange **178** is locked in position when hole **185** is in positional registration with hole **184** and locking bar **173** end **139** is passed through both. The swinging locking bar includes hollow side section **172** and inner, preferably solid, side section **173**, which is telescopic within outer hollow side section **172**.

FIG. **18** shows another embodiment **150** of this invention wherein the locking base has been integrated with the note-

14

book computer or other personal electronic device lock. Clamp **153** locks onto work surface **85** as described in a previous embodiment with a separate locking base **81** (see FIGS. **13-14**). Upright brackets **151** and **152** with bar **83** between capture the notebook computer or other personal electronic device display which is then locked via swinging locking bar **84** and a key lock (not shown).

A related embodiment in FIG. **19** shows integrated base/computer or other personal electronic device lock **160** which has one or more pivot points **164** and **166** (on base part **167**). Link **165** now pivots in relation to clamp section **163** such that the notebook computer or other personal electronic device lock **160** can be more conveniently positioned on work surface **85**.

In FIG. **19**, for example, clamp **163** is placed on the edge to the side of computer or other personal electronic device lock base **167** instead of directly in front of it as would be necessary in the embodiment of FIG. **18**.

The preferred low profile locking base embodiment of this invention for consumer use is detailed in FIGS. **20-27**.

FIG. **20** shows a low profile locking base **200** with narrow base **202** and low rise back **201**. It is screwed to work surface **285** via fasteners, such as screws **203**. Locking bar **284** with optional rubber or elastomer grommets **205** and machined end **288** is used to lock the display of a notebook or laptop computer or other personal electronic device (not shown) to locking base **200**. End **288** is passed through hole **204** and locked with pin lock **110**. Key **111** is used to unlock and remove the computer or other personal electronic device.

The preferred simpler method of use of a locking base is not to screw it down as shown in FIG. **20** but instead to create a portable locking kit by adding a clamp **211** and cable **210** as shown in FIG. **21**.

Due to the low profile design with a narrow base, all components of the portable kit conveniently fit into a tubular carrying case (not shown).

FIG. **21** also shows Clamp **211** having a fastener, such as a screw subassembly, including screw **212** and short container, such as a cylinder **216**, with transverse cable attachment hole **213**. At the first end of cable **210** is a ferrule **215** with a transverse hole. This fits through hole **213**. The cable is threaded through hole **213** after clamp **211** is secured using the appropriate tool to tighten screw **212**. The distal end of cable **210** has ferrule **214** with enlarged end which does not fit through hole **213**.

FIG. **22** shows the arrangement more clearly. It is noted that cylinder **216** has distal hole **220** which accommodates the screw head and also has a screw clearance hole **221** on its top surface. After cable **210** is threaded through hole **213**, a tool cannot reach screw head **222** to loosen clamp **211** since access is denied through distal hole **220**. After cable **210** is installed through cylinder **216**, the end **288** of locking bar **284** is passed through the transverse hole in ferrule **215** prior to locking bar **284** to base **200**.

In an alternate embodiment of the clamp screw subassembly no tool is required to tighten or loosen clamp **211**.

For example, an exploded view of subassembly **230** is shown in FIG. **23** with end cap **231** pushed down over clamp screw **233** and press fit into the end of knob **235**. Optional pins **238** can be driven radially to insure positive attachment. Cap **231** has screw clearance hole **232** at its center. Screw **233** becomes captive as a subassembly with tall head **234** within knob **235** once cap **231** is attached. Offset transverse hole **237** in knob **235** goes through both walls and is sized for cable attachment.

FIG. **24** shows the underside of cap **231** revealing hexagonal recess **240** sized to engage bolt head **234**.

15

FIG. 25 is a top view of subassembly 230. In the side crosssection of FIG. 26, bolt head 234 is seated in recess 240 of cap 231. This is prior to the insertion of cable 210 through holes 237. Clamp 211 can be tightened in this depicted configuration by turning knob 235 since recess 240 acts as a socket wrench to bolt 233. It is noted also that the size of head 234 interferes with the placement of hole 237 thereby preventing insertion of cable 210 while head 234 is seated in recess 240.

If knob 235 is pushed up as shown in FIG. 27, cable 210 can now be easily inserted through holes 237 adjacent to screw 233 and spacing head 234 away from recess 240. In this configuration with cable 210 installed through knob 235, if turned, knob 235 will spin freely regardless of the up or down forces exerted. Clamp 211 can only be removed after cable 210 is removed and head 234 is re-seated in recess 240. In lieu of a non-standard screw 233 with tall head 234, a standard hex screw can be used with a nut screwed up against the head and adhesively bonded as a unit. A washer between the nut and the screw head would only enhance the operation creating a more positive barrier with cable 210.

In an alternate protruding member locking embodiment of this invention, spikes, security rods or strips are used to secure a personal electronic device, such as a notebook computer, cellphone, personal digital assistant (PDA) or electronic music player (i.e. iPod®).

For example, in FIG. 28, a notebook computer or other personal electronic device with base 275 and display 276 is shown. One of the three through-holes is required for this embodiment. Hole 278 is at the hinge line, while hole 279 is through the display housing; hole 277 is diagonally through one of the front or rear corners of the base.

In the alternate locking embodiment shown in FIG. 28A, a notebook computer 500 has a through hole 503 in the display portion which aligns in positional register with through hole 504 in the base or keyboard portion 502 when in the closed position. A protruding lock, such as, for example, padlock 505 with elongated hasp 506, is used to prevent display portion 501 from being opened in a usable position. In addition, if a secure cable with a loop on its distal end is in the vicinity, this loop can also be engaged by hasp 506 thereby securing computer 500 to fixed location. Other protruding locks, such as spikes, security rods or strips, can also be used to lock display portion 501 with keyboard portion 502 when in the closed position.

FIGS. 28B-D illustrate yet another locking embodiment for notebook computer 515 with display 516 which has a security hole 517 in the upper right corner of display portion 516. Hole 517 is a through hole. FIGS. 28C and 28D illustrate how the apparatus of FIG. 29 (without spike 285) is used to secure computer 515. Ferrule 286 is passed through hole 517 and locked by pin lock 110. In this manner cable 210 attaches computer 515 to secure table top clamp 211 or to another securing member, such as a table leg of the work surface upon which notebook computer 500 is placed.

It is further noted that ferrule 286 can also be used to lock notebook computer 500 in place in the closed position as in FIG. 28A, or the hasp 506 of FIG. 28A can also be used to lock the display portion 516 of notebook computer 500 instead of ferrule 286 and pin lock 110 shown in FIG. 28C.

FIG. 29 shows locking rod or spike 285 which is inserted in any of the three hole locations discussed. Ferrule 286 with a groove near its distal end is then inserted through the transverse hole of spike 285 and locked with pin lock 110. Ferrule 286 is securely attached to cable 210 which had been passed through knob 235 after clamp 211 had been tightened at the

16

edge of a table or desk top. In this manner, the illustrated notebook computer or other personal electronic device is secured via a secure cable.

In a variation of this embodiment, the separate spike 285 is replaced by a captive security rod 291 as shown in FIG. 30. Note that rod 291 may be attached either to one end of the hinge or alternatively to the top surface of the base of computer or other personal electronic device 290 at any convenient location where space permits. Rods 291 are stored in a recessed position with only a small knob protruding so that they may be easily grasped to unlock into the extended position to expose a transverse hole. Ferrule 286 and lock 110 are then used in the same manner as with the separate spike 285.

In another spike variation shown in FIG. 31, long spike 296 is used to secure computer or other personal electronic device 294 which has a hole 295 through its base. Hole 295 is placed over pre-existing hole 298 through table top 293; then spike 296 is inserted such that transverse hole 297 is accessible beneath table top 293. Then transverse pin 299 with a groove adjacent its distal end is inserted through hole 297 and locked with pin lock 110. Thus this variation locks a notebook computer or other personal electronic device using a spike without the aid of a cable.

In another embodiment shown in FIG. 32 with a flexible locking strip 301, a detail of notebook computer 304 with display 305 and keyboard portion 306 is shown adjacent to clamp 302. Flexible locking strip 301 is shown prior to insertion through the hinge gap between display 305 and keyboard 306 (not shown) and further between bottom jaw 314 and top movable jaw 312 of clamp 302.

In lieu of being inserted within a hinge gap, flexible locking strip 301 may be inserted within a thin, longitudinally extending slot, similar to holes 277, 278, 279 for rod 285 of FIG. 29.

FIGS. 33, 36 and 37 show other features of clamp 302 with movable top 311 and stationary base 313. Locking strip 301 is clearly shown in top view and side view in FIGS. 34 and 35 respectively. Wedge stop 325 is shown at one the proximal end with narrow rectangular strip 326 at the distal end. Wedge stop 325 is preferably plastic which is bonded to strip 326 as by overmolding. It is noted that base portion 313 of clamp 302 is typically screwed to work surface 303 via screws 322, however, alternatively security cable 320 with secured distal end (not shown) can be used.

Gripping means, such as serrations 337 in FIG. 36, form lower static jaw 314 of FIGS. 32 and 33; they engage strip 301. Hole 336 is used for optional cable 320. Holes 322a accommodate fasteners 322, such as screws. Rectangular holes 335 accept tabs 339 of upper movable jaw 311 to form a hinge. The vertical wall 313a of base 313 can be alternatively joined to movable section 311 via ordinary hinges.

As in FIGS. 38 and 39, spring 319 tends to keep jaws 312 and 314 slightly apart unless lock 317 is locked via key 318. In that case if key 318 is rotated while moving member 311 is pressed down, lock tang 331 will engage lock recess 316 at the distal end of spring 319; recess 316 is attached to base 313. This action will lock locking strip 301 between jaws 312 and 314. Note that lock 317 is attached to hinged part 311 via a fastener, such as lock nut 330.

FIGS. 40-43 show notebook computer 304, cellular phone 346, PDA 347 and personal DVD player 348 each with hinge gap 345. In addition, the entry path of locking strip 301 is shown by arrows in FIG. 40.

FIG. 40 also shows a further alternate embodiment whereby the housing of notebook computer 304 contains a slot 326 for insertion of a flexible or rigid locking strip 328 therethrough.

17

FIGS. 44-47 relate to an alternate embodiment of clamp 355 which incorporates a leaf spring 358 to impart locking force to locking strip 301 when shackle 366 of padlock 365 is passed through lock loops 362 and handle loop 376 (as in FIG. 46). In this embodiment, shallow recess 359 with transverse serrations aggressively grasps strip end 326 under bending force of spring 358, which itself can have optional transverse serrations on its contact surface.

When handle 357 is free to swing up, strip end 326 can be easily passed between brackets 371 which are spaced apart a distance "W" (as in FIG. 45) to accommodate the width of strip end 326. Base 356 is secured to work surface 303 via fasteners, such as screws 369, which are passed through countersink holes 367 (as in FIG. 45). Leaf spring 358 is swaged or brazed at region 363 within slot 373 of handle 357. Hole 375 in loop 376 accommodates shackle 366. It is noted that spring 358 has to be bent somewhat for handle 357 to be in registration with the holes in padlock brackets 362. This bending also permits clamp 355 to accommodate strip ends 326 of varying thicknesses. Also, with respect to the geometry of spring 358 in FIG. 44, if a pulling force is placed on locking strip 301, frictional forces will tend to rotate the free end of spring 358 in a counter-clockwise direction thereby increasing clamping force on strip end 326; this further counteracts the pull-out force. Since spring 358 is wider than handle 357 (as in FIG. 47), centering washers 377 are used on either side of it to increase the combined width to X which is just slightly smaller than W. Rivet 360 in brackets 361 acts as an axle for handle 357; hole 372 is a clearance fit for rivet 360.

FIG. 48 illustrates alternate embodiment locking strip 390 with locking wedge 391, strip 393 and end hole 392. Locking strip 390 may be rigid or flexible.

Dashed lines 305 of FIG. 48 show the position of a computer display if this is being secured. Added hole 392 permits at least three non-clamp locking methods to be used. These are illustrated in FIGS. 49-51; for clarity, no item is shown being locked in these FIGS. 49-51.

It is understood that instead of being inserted through a hinge gap, locking strip 390 may be first passed through a thin, longitudinally extending slot in the housing of the personal electronic device, such as a notebook computer, instead of a round hole provided for a rod 285 or 296, as is shown in FIGS. 29-31. In this case, the thinness of the slot 327 for strip 328 minimizes any intrusion into the interior of the walls of the personal electronic device, such as a notebook computer 305 and the like, with its intricate wiring located in a tight space within the walls of the notebook computer 305, or other personal electronic device.

The strip 390 may be a rigid rectangle or other geometric shape. Additionally strip 390 may be flexible. If flexible, strip 390 may pass through a slot in the housing of the personal electronic device, or if the device is hinged, through a hinge gap between the display of the device and the main body of the device being secured.

In FIG. 49, stud 395 is attached to and protrudes from work surface 303. Hole 392 is simply passed over the distal end of stud 395 and then the shackle of padlock 397 is passed through the transverse hole in stud 395 to lock strip 390.

In FIG. 50, secure cable 400 with collar 402 and a rigid stud at its distal end is used to secure strip 390. After the rigid stud

18

is passed through hole 392, cable lock 401 is snapped over the end of the stud thereby securing strip 390.

In FIG. 51, free cable 405 with lock member 406 permanently attached is passed through hole 392. Since member 406 is a bulge larger than the diameter of hole 392, locking strip 390 will be secured when the distal end of cable 405 is looped or otherwise secured to work surface 303 or to some point adjacent to it.

In the foregoing description, certain terms and visual depictions are used to illustrate the preferred embodiment. However, no unnecessary limitations are to be construed by the terms used or illustrations depicted, beyond what is shown in the prior art, since the terms and illustrations are exemplary only, and are not meant to limit the scope of the present invention.

It is further known that other modifications may be made to the present invention, without departing the scope of the invention.

I claim:

1. A locking assembly for a notebook computer or other personal electronic device having a visual display portion attached to a keyboard base portion by a hinge, comprising: a first aperture located on a first surface of said device, and a second aperture located on a second surface of said device; a locking base secured to a working surface; an elongated locking member attached at a first end to said locking base and having a second end extending through an opening in a member protruding completely through at least a one part of said device by being inserted into said first aperture entering an interior of said device, and then being inserted into said second aperture and exiting an interior of said device; and, a lock for securing said locking member to said protruding member.

2. The locking assembly as in claim 1 wherein said at least one part is a visual display portion of the device.

3. The locking assembly as in claim 1 wherein said at least one part is a keyboard display portion of the device.

4. The locking assembly as in claim 1 wherein said at least one part is a visual display portion and a keyboard portion of the device, wherein said opening extending through said visual display portion is in positional register with said opening in said keyboard portion of said device.

5. The locking assembly as in claim 4 wherein said protruding lock is an elongated hasp of a padlock.

6. The locking assembly as in claim 4 wherein said protruding lock is a ferrule extending through said visual display portion or said keyboard portion of said device.

7. The locking assembly as in claim 4 further comprising a cable engaging said lock to secure said device to a work surface upon which notebook computer is placed.

8. The locking assembly for a notebook computer or other personal electronic device as in claim 1 further comprising said locking base being a clamp having wrapped over an edge of a work surface upon which said device is used;

said clamp further including a locking pin movable upward into a locking position against an underside of said work surface;

said locking pin locked in place by a further lock preventing removal of said locking pin away from said underside of said working surface.
