Allergic Rhinitis: Clinical Development Programs for Drug Products

DRAFT GUIDANCE

This guidance document is being distributed for comment purposes only.

Comments and suggestions regarding this draft document should be submitted within 90 days of publication of the *Federal Register* notice announcing the availability of the draft guidance. Submit comments to Dockets Management Branch (HFA-305), Food and Drug Administration, 5630 Fishers Lane, rm. 1061, Rockville, MD 20852. All comments should be identified with the docket number listed in the notice of availability that publishes in the *Federal Register*.

Additional copies of this draft guidance document are available from the Drug Information Branch, Division of Communications Management, HFD-210, 5600 Fishers Lane, Rockville, MD 20857, (Tel) 301-827-4573, or from the Internet at http://www.fda.gov/cder/guidance/index.htm.

For questions on the content of the draft document contact Martin H. Himmel, 301-827-1050.

Allergic Rhinitis: Clinical Development Programs for Drug Products

I. INTRODUCTION

8 9

7

1 2 3

4

5 6

10 This guidance is intended to assist sponsors of new drug applications (NDAs) in designing 11 development programs for oral and intranasal drug products for the treatment of allergic rhinitis 12 in children and adults. The guidance addresses issues of study design, effectiveness, and safety 13 for new drugs being developed for the treatment of seasonal allergic rhinitis (SAR) and perennial 14 allergic rhinitis (PAR).

- 15
- 16

17 II. BACKGROUND

18

19 Information about the pathophysiology and treatment of allergic rhinitis and its subtypes, SAR 20 and PAR, has grown markedly in the past decade. The recommendations in this guidance are 21 based on a careful assessment of important issues raised in the review of both adult and 22 pediatric allergic rhinitis clinical trials and the Agency's current understanding of the mechanism 23 of the two related disorders of SAR and PAR. The pathophysiology of SAR and PAR are very similar in terms of the chemical mediators produced and end-organ manifestations, with 24 25 differences between the two entities primarily based on the causes and duration of disease. The study design issues pertaining to SAR and PAR trials are also very similar. Thus, these two 26 27 categories are treated collectively in this guidance as *allergic rhinitis*, with differences in 28 recommendations for the design of SAR and PAR trials indicated. 29 30 When finalized, this document will replace the previous Points to Consider: Clinical Development Programs for New Nasal Spray Formulations (January 1996). Sponsors are 31 32 encouraged to discuss details of study design and specific issues relating to individual drug 33 products with division review staff prior to conducting clinical trials. 34 35 Allergic rhinitis includes both nasal and non-nasal symptoms. The main nasal symptoms of

36 allergic rhinitis are nasal itching (i.e., nasal pruritus), sneezing, rhinorrhea, and nasal congestion.

37 Nasal pruritus and sneezing are induced by sensory nerve stimulation, whereas congestion

¹ This guidance has been prepared by the Division of Pulmonary and Allergy Drug Products in the Center for Drug Evaluation and Research (CDER) at the Food and Drug Administration. This guidance document represents the Agency's current thinking on clinical trial design of seasonal and perennial allergic rhinitis studies in adults and children. It does not create or confer any rights for or on any person and does not operate to bind FDA or the public. An alternative approach may be used if such approach satisfies the requirements of the applicable statutes, regulations, or both.

38	results	from	a vasodilation with resultant engorgement of cavernous sinusoids. Rhinorrhea can be
39	induced	d by	increased vascular permeability as well as direct glandular secretion. Important non-
40	nasal sy	ympt	toms commonly associated with allergic rhinitis include eye itching, eye tearing,
41	itching	ofe	ars and/or palate, and eye redness.
42			
43	A grow	ving	number of chemical mediators are believed to contribute to allergic rhinitis. They
44			amine, leukotrienes (LTC ₄ , LTD ₄ , and LTE ₄), kinins, prostaglandins, chemotactic
45			uropeptides (e.g., substance P, CGRP, VIP), interleukins -1, -5, -6, -8, and tumor
46			ctor- α . Additional mediators with a potential role in allergic rhinitis will likely be
47			the future. Despite different causes and temporal patterns of disease, the same
48			hemical mediators appear to be regulators of the responses in seasonal and perennial
49	allergic	rhin	itis. It is for this reason that distinctions between SAR and PAR in terms of clinical
50	trial des	sign	will be made only in clinically relevant areas.
51			
52	III.	OV	VERALL CONSIDERATIONS – ADULT PROGRAM
53			
54		А.	New Molecular Entity
55			
56			1. Number of Trials
57 58			For approval of a new molecular entity in adult and adolescent patients (age 12
59			years and older), at least two adequate and well-controlled phase 3 clinical trials are
60			recommended to support either the SAR or PAR indication. Alternatively, a
61			sponsor can submit one SAR and one PAR trial in support of both the indications, if
62			both trials are adequate and well-controlled phase 3 trials and both trials
63			demonstrate the safety and effectiveness of the drug for the indications.
64			
65			2. Dose
66			
67			The dose-response relationship for the new drug should be evaluated in these trials.
68			These trials, or other supporting trials, should identify a <i>lowest effective dose</i> for
69			the drug (i.e., the lowest dose that demonstrates a statistically significant difference
70			between the to-be-marketed drug and the placebo). This recommendation is
71			particularly important for intranasal corticosteroids.
72			
73			3. Safety Monitoring
74			
75			These trials should also address safety concerns, such as monitoring for adverse
76			events, performing routine laboratory tests (i.e., blood chemistry, liver function tests,
77			complete blood count with differential), urinalyses, and electrocardiograms, as
78			appropriate. For SAR and PAR phase 3 trials, routine laboratory tests should be
79			obtained in study patients at least at the initial screening and at the last visit.
80			

5

81	For some allergic rhinitis drugs (particularly drugs in the antihistamine class), part of
82	the safety program should include a thorough cardiac safety evaluation, with studies
83	performed in both men and women. A suggested approach would include:
84	
85	• Screening and end-of-treatment ECGs, including a careful assessment of the
86	QT _c interval and any T wave abnormalities, as read by a ECG reviewer blinded
87	to study treatment.
88	
89	• Human dose escalation studies that evaluate serial ECGs at drug exposures up
90	to dose-limiting toxicity of any organ system.
91	
92	• For drugs metabolized by the cytochrome P450 3A4 system, drug interaction
93	studies performed with both a macrolide and azole antibiotic.
94	-
95	• 24-hour Holter monitoring performed before, during, and, as appropriate, on
96	completion of the efficacy trials for allergic rhinitis drugs suspected to have an
97	effect on QT _c intervals from previous studies.
98	
99	In addition to the studies described above, case report forms and study reports
100	should include a detailed description of all serious cardiac adverse events and
101	pertinent ECGs.
102	-
103	Sponsors are encouraged to contact the review division regarding appropriate
104	cardiac safety monitoring for their respective drug development programs.
105	
106	For many allergic rhinitis drugs, some assessment of the degree of sedation
107	compared to the placebo should be provided in the safety database. This should
108	primarily be based on individual patient adverse event reports of sedation and/or
109	drowsiness (or similar terminology, as defined by the sponsor's adverse event
110	dictionary).
111	
112	Generally, long-term safety data should include at least 300 patients evaluated for 6
113	months and 100 patients evaluated for 1 year. The overall patient database should
114	include at least 1500 patients. (See the International Conference on Harmonisation
115	guidance on the Extent of Population Exposure Required to Assess Clinical
116	Safety for Drugs Intended for Long-term Treatment of Non-Life Threatening
117	Conditions (March 1995).)
118	
119	4. Corticosteroid Issues
120	
121	Important safety issues for intranasal corticosteroids that would ordinarily be
122	addressed in the adult clinical program include:
123	

6

124	• Assessment of adrenal function using either timed urinary free cortisol level
125	measurements (i.e., 12-hour or 24-hour), or 24-hour plasma cortisol AUC
126	levels pretreatment and after at least 6 weeks post-treatment with study
127	medication. A placebo and an active control (e.g., oral prednisone) should be
128	included in these studies.
129	
130	• Evaluation for possible cataract formation by slit-lamp examination, pre- and
131	post-treatment.
132	
133	• Evaluation for glaucoma, using intra-ocular pressures monitored pre- and post-
134	treatment.
135	
136	B. Change in Formulation and/or Device
137	
138	1. Oral Formulations
139	
140	For a change in an oral dosage form from an approved oral formulation to a new
141	oral formulation of the same drug substance, an alternative to conducting the new
142	molecular entity program described above is to demonstrate bioequivalence
143	between the two formulations. This is based on pharmacokinetic comparisons (e.g.,
144	AUC, C_{max} , C_{min}) between the approved and to-be-marketed formulations. This
145	equivalence approach allows the indications and patient populations for the new
146	formulation to be the same as those described in the labeling of the approved
147	product. If a significant new excipient, not previously administered at comparable
148	levels to humans, is present in the new formulation, or if the tolerability of the new
149	formulation is otherwise in question, short- and possibly long-term safety data may
150	still be important for patients receiving the new formulation, even if bioequivalence is
151	demonstrated. Additional safety and efficacy trials may be necessary to support a
152	new formulation if bioequivalence is not demonstrated.
153	an ku na na ang ang ang ang ang ang ang ang a
154	2. Topical Nasal Formulations
155	*
156	For changes in formulation and/or device for a topical nasal product (e.g., aqueous
157	pump, spray), one of two approaches can be used to demonstrate the safety and
158	effectiveness of the new drug product: (1) establishment of comparability between
159	the new and previously approved (reference) formulation, or (2) development of the
160	new formulation and/or device by a usual program for a new drug product (i.e.,
161	stand-alone approach).
162	
163	Comparability Approach
164	
165	To demonstrate clinical comparability between the new and reference formulations,
166	comparison of the dose-response curves of these two formulations in a single

7

167	efficacy and safety trial is recommended. Two doses of each formulation, in
168	addition to placebo, are desirable for dose-ranging determination. The dose-
169	ranging study should be designed to permit determination of how doses of the new
170	formulation compare to the approved doses of the reference formulation with regard
171	to onset of action and effectiveness. Comparative pharmacokinetic (PK)
172	measurements (C _{max} , T _{max} , and AUC) should be included in this trial, as appropriate
173	and technically feasible. If the reference formulation is indicated for both SAR and
174	PAR, the dose-ranging trial can be performed in patients with either SAR or PAR
175	(see section V of this guidance, Protocol Issues and Elements, for recommended
176	trial durations). If the reference formulation is approved for indications in addition
177	to SAR and/or PAR (e.g., nasal polyps or nonallergic rhinitis) no additional studies
178	are needed to support the same indications for the new product, if comparability, as
179	described above, is well established between the new and reference formulation.
180	
181	Stand-Alone Approach
182	
183	An alternative approach or stand-alone approach for evaluating a topical nasal
184	drug product with a formulation change could be a single, dose-ranging, placebo-
185	controlled efficacy and safety trial of the new formulation in patients with either SAR
186	or PAR. A single dose of the reference formulation as a positive control is
187	recommended. Demonstration of effectiveness for either of these two clinical
188	indications would allow labeling to include efficacy for both, if the reference
189	formulation already had labeling for both. If additional indications (e.g., nasal
190	polyps and nonallergic rhinitis) previously approved for the reference formulation
191	are sought for the new formulation, a single clinical trial for each additional indication
192	is recommended. Furthermore, as with the comparability approach,
193	determination of the pharmacokinetics of the drug is recommended during the
194	stand-alone approach and can be performed during the efficacy trial, if feasible.
195	
196	3. Safety Monitoring
197	
198	For both oral and topical nasal formulation programs described above, safety
199	monitoring should be included for the duration of the trials. This would include
200	evaluation of adverse clinical events, routine laboratory tests (i.e., blood chemistry,
201	liver function, complete blood count with differential), urinalysis, and ECGs, as
202	appropriate.
203	
204	In either of these formulation programs, demonstration of long-term safety may still
205	be important, if new inactive ingredients have been added that could affect safety, or
206	if the new formulation and/or device results in higher systemic exposure to active
207	ingredients compared to the approved product. In addition, if pharmacokinetic data
208	for the formulations are not feasible, long-term safety data for the new formulation
209	may be recommended. If necessary, long-term safety may be established by

may be recommended. If necessary, long-term safety may be established by

8

210 documenting exposure of at least 200 patients to the new formulation for 6 months 211 at the dosage proposed for marketing. Due to the duration, these studies are 212 generally conducted in patients with PAR. An active control arm, consisting of a 213 single dosage level of the reference formulation, is recommended. Symptom-guided 214 dosage adjustment by study patients during the long-term open label study should 215 be avoided, as this complicates analysis of the safety data. To minimize dropouts 216 and to address ethical considerations, stratification of patients and dosage according to symptom severity is acceptable at the start of the open label study. However, a 217 218 sufficient number of patients who receive the highest dose proposed for marketing 219 should be included. Rescue medication should not include other intranasal drugs or 220 intranasal products. 221

222

223

4. Corticosteroid Issues

224 For corticosteroids, if the new formulation causes higher systemic exposure to the drug substance than other formulations (either intranasally or orally inhaled) already 225 marketed or under development for which an adequate assessment of HPA axis 226 227 effects has been conducted, or if pharmacokinetic data on these other formulations is unavailable, an evaluation of the effect of the new formulation on the HPA axis is 228 229 strongly recommended. For HPA axis evaluation, measurement of timed (12- or 230 24-hour) urinary free cortisol levels or serum cortisol AUC before and after 6 231 weeks of treatment are the preferable methods of assessment. If the sponsor plans 232 to claim comparability between the reference and new formulations, and a pharmacokinetic comparison of the two products is not available, comparison with 233 234 the highest marketed dose of the reference formulation is recommended.

- For a change in a device, data on the performance and reliability of the new device over the period of intended use may need to be provided.
- 237 238 239

235 236

IV. OVERALL CONSIDERATIONS – PEDIATRIC PROGRAM

240 241 242

A. New Molecular Entity or New Pediatric Indication

243 The pediatric age ranges proposed for a drug product, particularly for very young 244 patients, should be justified by the sponsor based on the presence of disease and the 245 need for treatment in that age group. Drugs indicated for the treatment of allergic rhinitis 246 are used in children below the age of 2 years; therefore, a complete pediatric program 247 should evaluate the safety of antihistamines in children down to age 6 months. Similarly, based on clinical use experience, the safety of intranasal corticosteroids, cromolyn-like 248 249 drugs, and anticholinergics should be evaluated in children down to age 2. Sponsors 250 are encouraged to discuss the specifics of pediatric programs with the division on a 251 case-by-case basis.

252

MEDA_APTX03502735

9

1.	Drugs Not	Previously	Studied	in Adults

For approval of a new molecular entity in pediatric patients (patients younger than 12 years), the number of studies recommended depends on whether the drug is already approved in adult patients. For a new molecular entity (NME) not previously approved or adequately studied in adults, the clinical program would be the same as that described for adults. This would include two adequate and well-controlled safety and efficacy trials along with appropriate long- and short-term safety data. For an NME intranasal corticosteroid, the performance of a growth study (possibly postapproval) is recommended in order to assess the potential of the corticosteroid to suppress growth in children.

256

257 258

259

260 261

262

263

2. Drugs Already Studied in Adults

For drugs already approved and/or adequately studied in adults but not yet studied in children, an appropriate pediatric dose should be determined. In addition, adequate short- and long-term safety information for the proposed pediatric age group should be provided. For oral formulations where a reasonable pharmacokinetic/pharmacodynamic (PK/PD) link for effectiveness has been established, PK data from children can be used to determine comparable exposure to adult patients, and therefore the appropriate pediatric dose.

For intranasal formulations, the performance of efficacy studies in pediatric patients is recommended, since plasma drug levels are not consistently detectable or reliable as measures of local bioavailability and topical efficacy.

3. Safety Data

Typically, 3 months of additional specific pediatric safety data for intranasal products and 1 month of additional safety data for oral products are recommended. These data should be collected in placebo controlled trials. However, the duration and number of pediatric patients exposed to the study drug for safety monitoring should be determined on an individual basis for each drug, based on anticipated side effects, pediatric PK data, and safety concerns.

4. Corticosteroid Issues

For intranasal corticosteroids, performance of a 6-week HPA axis study is recommended. Because of ethical concerns about the use of oral prednisone as an active comparator in adrenal response studies in children, inclusion of an oral prednisone arm in pediatric adrenal assessment studies is not typically recommended. However, inclusion of an active comparator arm (e.g., an intranasal corticosteroid approved in the pediatric population) is encouraged.

10

296		
297		Based on recent information that intranasal corticosteroids have the potential to
298		decrease growth velocity in children, a growth study is recommended for
299		prepubertal children as a phase 4 commitment, if not before. If the studies are to be
300		performed postapproval, it may be useful for a sponsor to include a knemometry
301		study in the NDA submission to provide some PD growth data for consideration
302		during the initial review. Growth studies should evaluate growth before and after
303		treatment with the intranasal corticosteroid, using stadiometry to assess growth.
304		Such a growth study should enroll patients with allergic rhinitis, incorporate a run-in
305		period, and be placebo controlled. Sponsors should ensure that an adequate
306		sample size is studied and that there is a reasonable duration of treatment (ordinarily
307		1 year). These recommendations allow for a better estimate of the decrease in
308		growth velocity seen in association with intranasal corticosteroid use. Information
309		on a clinically significant change in growth derived from knemometry studies should
310		not be used to determine the expected change in growth velocity for longer-term
311		studies that use stadiometry to measure growth. This is because of the nonlinearity
312		of growth and differences in study durations for these two techniques. Sponsors are
313		encouraged to discuss the details of their pediatric growth study design with the
314		review division.
315		
316		B. Change in Formulation and/or Device
317		
318		In situations where a sponsor has conducted a change in the formulation and/or device
319		comparability program in adults, as described above, additional pediatric efficacy
320		studies may not be required if:
321		
322		• The safety, efficacy, and PK of the new formulation are comparable to that of the
323		reference formulation in adults, and
324		
325		• The reference formulation has been approved for use in an appropriate pediatric
326		age range.
327		6 6
328		However, depending on the specific changes that were made in the formulation and/or
329		device, additional safety and/or use studies in children may be needed.
330		······································
331	V.	PROTOCOL ISSUES AND ELEMENTS
332		
333		A. Trial Design
334		
335		In the development programs of allergic rhinitis drugs, otherwise well-designed and
336		well-conducted studies may occasionally fail to show effectiveness. This is due in part
337		to the subjective nature of the assessments and spontaneous variability in the disease.
220		

338 This observation makes the use of a placebo control of paramount importance, since a

11

339		pos	sitive-control equivalence trial cannot be interpreted in such a situation. If the intent is
340		to s	show that the new product is significantly more effective than an approved active
341		con	ntrol, a positive-control study may be sufficient.
342			
343		Th	e following are general recommendations on trial design for phase 3 allergic rhinitis
344			AR and PAR) trials in adults and adolescents (older than 12 years) and children
345			bunger than 12 years).
346		<i>v</i>	
347		•	These studies should be double-blind, placebo-controlled, and parallel group,
348			preferably with a placebo run-in period.
349			F
350		•	Inclusion of an active control arm is recommended for both reformulation programs
351			(as described above) and for new drug development programs. For the new drug
352			development program, the positive-control study is helpful in interpreting trials in
353			which there is not a demonstrable difference between the test drug and the placebo.
354			which alore is not a demonstrative anterenee between the test and and praceto.
355		•	The duration of the double-blind treatment period should be at least 2 weeks for
356		-	SAR trials and 4 weeks for PAR trials.
357			
358		•	For SAR trials, the study protocol should discuss plans for measuring pollen counts
359		•	at the different study centers. The study report should document the exposure of
360			patients to the relevant allergens during the study period. It may also be helpful to
361			collect data on the number of rainy days during the trial and the extent of patient
362			exposure to outdoor air.
362			exposure to outdoor an.
363			For SAD trials rendomization of nationts within each contar into the double blind
365		•	For SAR trials, randomization of patients within each center into the double-blind partian even a short time period ($a = -2.4$ days) is an even period, as this generally
			portion over a short time period (e.g., 3-4 days) is encouraged, as this generally
366			reduces variability in allergen exposure.
367			Many noticute with DAD may have concentions CAD. Therefore DAD trials should
368		٠	Many patients with PAR may have concomitant SAR. Therefore, PAR trials should
369			be conducted during a time when relevant seasonal allergens are less abundant and
370			therefore less likely to influence results of the trial (i.e., late fall and winter).
371	-	-	
372	В.	Inc	clusion Criteria
373			
374		٠	For SAR effectiveness trials, patients should have a history of SAR for a minimum
375			of 2 years before study entry. Documentation of sensitivity by positive skin testing
376			(by prick or intradermal methods) or by adequately validated in vitro tests for
377			specific IgE (e.g., RAST, PRIST) to the relevant seasonal allergen for the
378			geographic area of the study within 12 months prior to enrollment is recommended.
379			A positive skin test is generally defined as a wheal ≥ 3 mm larger than the diluent
380			control for prick testing or \geq 7 mm larger than the diluent control for intradermal

12

 For PAR effectiveness trials, allergy to perennial allergens (e.g., dust mites, cockroaches, cats, dogs, molds) should be demonstrated in study patients by prick or intradermal skin testing (using the criteria for positivity above) or by adequately validated in vitro tests for specific IgE (e.g., RAST, PRIST). These tests should be done during the 12 months before enrollment. The patient should have a relevant allergy history to the tested allergen. For approximately 1 month preceding enrollment in the study, patients should not start immunotherapy or have a change in dose, and they should maintain the same dose throughout the trial. Patients enrolled in treatment studies (as opposed to prophylaxis studies) should be experiencing symptoms meeting or exceeding an appropriate minimum level at the time of study enrollment. This could be ensured by assessing the severity of the tengiority of individual symptoms, as defined by the study's symptom scoring scale. C. Exclusion Criteria Asthma, with the exception of mild intermittent asthma (see the 1997 NAEPP guideline on asthma severity criteria), to lessen confounding by asthma medications or super-potent topical corticosteroids Use of long-acting antihistamines Use of long-acting antihistamines Prohibited medications or inadequate washout periods (for certain classes of medications). The following vashout periods are generally sufficient: Intranasal or systemic corticosteroids (1 month) Intranasal or systemic conticosteroids (3 days) Intranasal or systemic devide, odays) Loratadine (10 days). Documented evidence of acute or significant chronic sinusitis, as determined by the 	381 382		testing. Positive in vitro tests are determined by the standards of the individual reference laboratory.
 For PAR effectiveness trials, allergy to perennial allergens (e.g., dust mites, cockroaches, cats, dogs, molds) should be demonstrated in study patients by prick or intradermal skin testing (using the criteria for positivity above) or by adequately validated in vitro tests for specific IgE (e.g., RAST, PRIST). These tests should be done during the 12 months before enrollment. The patient should have a relevant allergy history to the tested allergen. For approximately 1 month preceding enrollment in the study, patients should not start immunotherapy or have a change in dose, and they should maintain the same dose throughout the trial. Patients enrolled in treatment studies (as opposed to prophylaxis studies) should be experiencing symptoms meeting or exceeding an appropriate minimum level at the time of study enrollment. This could be ensured by assessing the severity of the majority of individual symptoms, as defined by the study's symptom scoring scale. C. Exclusion Criteria Asthma, with the exception of mild intermittent asthma (see the 1997 NAEPP guideline on asthma severity criteria), to lessen confounding by asthma medications or super-potent topical corticosteroids Chronic or intermittent use of inhaled, oral, intranuscular, intravenous, and/or potent or super-potent topical corticosteroids Prohibited medications or inadequate washout periods (for certain classes of medications). The following washcut periods are generally sufficient: Prohibited medications or inadequate washout periods (for certain classes of medications). The following washcut periods are generally sufficient: Intranasal or systemic corticosteroids (1 month) Intranasal or systemic corticosteroids (1 month) Intranasal or systemic entions (3 days) Intranasal or systemic corticosteroids (3 days) Intranasal or systemic cof acute or significant chronic sinusitis, as determi			reference laboratory.
385 cockroaches, cats, dogs, molds) should be demonstrated in study patients by prick 386 or intradermal skin testing (using the criteria for positivity above) or by adequately 387 validated in vitro tests for specific IgE (e.g., RAST, PRIST). These tests should be 388 done during the 12 months before enrollment. The patient should have a relevant 389 allergy history to the tested allergen. 390 • For approximately 1 month preceding enrollment in the study, patients should not 391 • For approximately 1 month preceding an appropriate minimum level at the time 393 dose throughout the trial. 394 Patients enrolled in treatment studies (as opposed to prophylaxis studies) should be 395 Patients enrolled in treatment studies (as opposed to prophylaxis studies) should be 396 experiencing symptoms meeting or exceeding an appropriate minimum level at the time 397 of study enrollment. This could be ensured by assessing the severity of the symptoms 398 for the primary endpoint and requiring at least moderate severity for all or the majority 399 of atudy enrollment. This could be clude possible study participants: 400 C Exclusion Criteria 402 • Asthma, with the exception of mild intermittent asthma (see the 1997 NAEPP			• For PAR effectiveness trials allerow to perennial allergens (e.g. dust mites

13

424	
425	• Chronic use of concomitant medications (e.g., tricyclic antidepressants) that would
426	affect assessment of the effectiveness of the study medication
427	
428	• A history of hypersensitivity to the study drug or its excipients
429	
430	Rhinitis medicamentosa
431	
432	• Presence of ocular herpes simplex or cataracts (for intranasal corticosteroid trials),
433	or a history of glaucoma (for intranasal corticosteroid or anticholinergic trials)
434	
435	• Planned travel outside the study area for a substantial portion of the study period by
436	potential participants
437	
438	D. Blinding
439	
440	Because allergic rhinitis trials are based on subjective endpoints, blinding is a critical
441	consideration. Blinding to study medication should be carefully described in the study
442	protocol (i.e., description of how the product is masked). If double-blinding is not possible,
443	a rationale for this should be provided, along with a discussion of the means for reducing or
444	eliminating bias. For nasal inhalers or pumps, a description of differences in appearance
445	between active and placebo treatments should be provided in the protocol (e.g., differences
446	in the device or in the odor or characteristic of the formulation) to help determine the
447	adequacy of the study blind.
448	
449	E. Formulations and Dosage Regimens
450	
451	For all classes of allergic rhinitis drugs, sponsors are encouraged to provide information in
452	the clinical study protocol on the specific formulations used for both the to-be-marketed
453	drug and the placebo, along with a description of the dosing regimen. The study report
454	should discuss whether the studied formulation was the to-be-marketed product, and if not,
455	how the safety and effectiveness of the studied formulation will be bridged to the to-be-
456	marketed formulation. If <i>bridging</i> of one formulation to another is proposed, information
457	about the formulation composition and study lots should be included in the study reports for
458	the respective products.
459	
460	F. Evaluation
461	
462	1. Assessment of Patient Compliance
463	
464	Information about how compliance with medication use will be determined and
465	documented throughout the trial and how noncompliance and/or missing data will be
466	dealt with, either in the form of patient exclusion or exclusion of data points (e.g., use of

14

467 last visit data carried forward) should to be provided in the study protocol and the study 468 report. 469 470 2. Assessment of Rescue Medication Use 471 472 If rescue medications are allowed during the study, documentation should be provided 473 in the study protocol on how rescue medication use will be analyzed in the different treatment groups. In the clinical trial report, a section presenting rescue medication use 474 475 in the different study medication groups should be provided. 476 477 3. Rating System 478 479 The preferred measures of effectiveness in allergic rhinitis trials are patient self-rated 480 instantaneous and reflective composite symptom scores. These summed scores 481 generally include the following four nasal symptoms: rhinorrhea, nasal congestion, nasal 482 itching, and sneezing, rated on a 0-3 scale of severity. Addition of non-nasal symptoms 483 to the composite score might be pertinent for certain drug products, such as systemically 484 active antihistamines, and should be discussed with the division on a case-by-case basis. 485 Exclusion of symptoms from the composite score may be allowable, based on the 486 drug's mechanism of action (e.g., exclusion of nasal congestion for antihistamines). 487 While both patient self-rated symptom scores and physician-rated scores can be 488 measured, the patient-rated scores are preferred as the primary measure of 489 effectiveness. 490 491 A common allergic rhinitis rating system that has been used in clinical trials is the 492 following 0-3 scale: 493 494 0 = absent symptoms (no sign/symptom evident) 495 1 = mild symptoms (sign/symptom clearly present, but minimal awareness; • 496 easily tolerated) 497 2 = moderate symptoms (definite awareness of sign/symptom that is 498 bothersome but tolerable) 499 3 = severe symptoms (sign/symptom that is hard to tolerate; causes interference • 500 with activities of daily living and/or sleeping) 501 502 Regardless of the scoring system chosen, a detailed description of the symptom rating 503 scale should be provided to patients. This should include instructions on proper 504 completion of the symptom diary and definitions of the different categories in the scale. 505 506 4. Recording Scores 507 508 Patients should record scores in a diary at least as often as the daily dosing interval. 509 Collection of both *reflective* symptom scores (i.e., an evaluation of symptom severity

15

510 after a predefined time period such as 12 hours) and instantaneous symptom scores 511 (i.e., an evaluation of symptom severity immediately before the next dose) is 512 recommended. Reflective symptom scores assess the overall degree of effectiveness 513 over a prespecified time interval, whereas instantaneous scores assess effectiveness at 514 the end-of-dosing interval. 515 516 DATA ANALYSIS ISSUES 517 VI. 518 519 A. Collection of Data 520 521 Symptom scores should be collected at baseline and daily over the course of the trial. 522 Collection of baseline symptom scores over several days immediately preceding patient 523 randomization will permit the evaluation of baseline comparability of the various 524 treatment arms, as well as the determination of treatment effects over time. 525 526 An appropriate primary efficacy endpoint is the change from baseline in the total nasal 527 symptom score (TNSS) for the entire double-blind treatment period (2 weeks for SAR 528 and 4 weeks for PAR). Depending on the drug class being evaluated, the TNSS is 529 defined as a composite score of at least three of the following four nasal symptoms: 530 rhinorrhea, nasal congestion, nasal itching, and sneezing. Inclusion of nasal congestion in 531 the TNSS may be appropriate for an intranasal corticosteroid or a decongestant, but 532 may not be for an antihistamine, anticholinergic, or cromolyn-like agent. 533 534 When designing allergic rhinitis protocols, sponsors are encouraged to provide the value 535 of a clinically meaningful change in the primary efficacy endpoint and the basis for this value. The statistical section of the protocol should also discuss powering of the trial 536 based on this relevant change. 537 538 539 In addition to evaluating the effectiveness of the drug over the entire double-blind 540 period, additional data presentations are helpful in evaluating the effectiveness of the 541 drug. These include: 542 543 Presenting the a.m. and p.m. symptom scores separately for both the reflective and • 544 instantaneous symptom assessments. 545 546 Presenting effectiveness data for the first few days of the trial separately for both the ۲ 547 reflective and instantaneous symptom assessments. This data presentation should 548 also separate the a.m. and p.m. scores. This allows some assessment of the onset 549 of action. 550

16

551 Presenting the efficacy data for each week individually for both the reflective and 552 instantaneous symptom assessments. This allows determination of both the onset of 553 action and the durability of the response over the course of the clinical trial. 554 Additional secondary efficacy analyses may include the individual patient-rated 555 556 symptoms that comprise the total symptom complex for the reflective and instantaneous 557 symptom assessments for both a.m. and p.m. In addition, other patient-rated symptoms and all physician-rated symptoms can be included as secondary efficacy endpoints. 558 559 **B.** Time to Maximal Effect 560 561 562 The time to maximal effect for an allergic rhinitis medication is the earliest time (days, 563 weeks) that the primary efficacy endpoint demonstrates the greatest numerical 564 difference from the placebo in change from baseline. Sponsors are encouraged to 565 include frequent symptom measurements to determine when patients may expect to see 566 the greatest benefit from use of the drug. 567 568 C. Duration of Effect (End-of-Dosing Interval Analysis) 569 570 Evaluation of the duration of effect, as measured by instantaneous symptom scores at 571 the end of the dosing interval, is highly encouraged to assess the appropriateness of the 572 dosing interval. A sponsor should demonstrate, as part of the drug development 573 program, a significant difference between drug and placebo at the end of the dosing 574 interval. 575 576 **D.** Onset of Action 577 578 The definition of the onset of action of an allergic rhinitis drug is the point at which 579 patients might reasonably expect to see a meaningful decrease in their allergic rhinitis 580 symptoms. Statistically, it is the first time point after initiation of treatment when the drug demonstrates a change greater than the placebo treatment from baseline in the primary 581 582 efficacy endpoint. This statistically significant difference between drug and placebo 583 should be maintained for some period from this point onward. 584 585 Because onset of action information in labeling may be used as a superiority claim, at 586 least two studies are recommended to support a particular onset of action claim. (It is 587 useful to assess onset of action during development, regardless of any proposed claims). 588 The two trials do not have to be identical in design, nor do they have to evaluate both 589 SAR and PAR. Since onset of action is in large part a pharmacodynamic issue, a 590 number of different study types could be used. Following are three study types that

PTX0025-00017

MEDA_APTX03502743

17

591

592

have been used.

593 594 595		• Standard phase 3 allergic rhinitis efficacy trials in which symptom scoring data are collected frequently for the first few days
596 597		• A single-dose, parallel group, placebo-controlled study of patients in a <i>park setting</i> in which patients are exposed to relevant outdoor seasonal allergens and, following
598 599		dosing, have nasal symptoms evaluated on an hourly basis
600		• An inhalation chamber study (also known as environmental exposure unit or EEU)
601		in which previously asymptomatic patients are exposed to a relevant allergen
602		(generally a seasonal allergen, such as ragweed) in a controlled indoor setting and,
603		following dosing, have their nasal symptoms evaluated on an hourly basis
604		
605 606		Onset of action data can come from any of these three study types. However, if EEU and/or park studies are used to support an onset of action claim shorter than the onset
607		of action seen in the phase 3 trials, these results should be replicated. This is due to the
608		shorter duration of these trials and the restricted setting and manner in which they are
609		conducted. In any case, information about onset of action derived from the phase 3
610		trials used to support approval should be included in the proposed package insert along
611		with any data from park or chamber studies, to reflect the real world setting of the
612		treatment trials.
613
