- 2) Lee is Unrelated to Carrier Aggregation
- 3) The POSA Would Not Combine Lee with the Feasibility Study
- 4) Petitioner Relies Improperly on Two Different Lee Embodiments for Claim 7

Claim Construction – “Carrier Aggregation”

1. An apparatus comprising:

a first amplifier stage configured to be independently enabled or disabled, the first amplifier stage further configured to receive and amplify an input radio frequency (RF) signal and provide a first output RF signal to a first load circuit when the first amplifier stage is enabled, **the input RF signal employing carrier aggregation** comprising transmissions sent on multiple carriers at different frequencies to a wireless device, the first output RF signal including at least a first carrier of the multiple carriers; and

a second amplifier stage configured to be independently enabled or disabled, the second amplifier stage further configured to receive and amplify the input RF signal and provide a second output RF signal to a second load circuit when the second amplifier stage is enabled, the second output RF signal including at least a second carrier of the multiple carriers different than the first carrier.

FIG. 3 shows a block diagram of an exemplary design of wireless device 110 in FIG. 1. In this exemplary design, wireless device 110 includes a transceiver 320 coupled to a primary antenna 310, receivers 322 coupled to a secondary antenna 312, and a data processor/controller 380. Transceiver 320 includes multiple (K) receivers 330_{aa} to 330_{ak} and multiple (K) transmitters 360_a to 360_k to support multiple bands, carrier aggregation, multiple radio technologies, etc. Receivers 322 include multiple (M) receivers 330_{ba} to 330_{bm} to support multiple bands, carrier aggregation, multiple radio technologies, receive diversity, MIMO transmission, etc.

Patent Owner Narrowed Claims to Overcome Hirose

Application/Control Number: 13/590,423

Page 3

Art Unit: 2631

Regarding claim 1, Hirose discloses an apparatus (FIG. 6 digital broadcast receiver) comprising:

a first amplifier stage configured to receive and amplify an input radio frequency (RF) signal and provide a first output RF signal to a first load circuit when the first amplifier stage is enabled (variable gain amplifier 15, corresponding to the claimed first amplifier stage, receiving input RF signal (e.g. satellite wave signal and ground wave signal) and providing an output to intermediate frequency demodulation stage (for ground wave), which corresponds to the claimed first load circuit (see column 5 lines 1-30 and FIG. 6) ;

the input RF signal comprising transmissions sent on multiple carriers at different frequencies to a wireless device, the first output RF signal including at least a first carrier of the multiple carriers (as recited above, the input RF signal comprising satellite wave signal and ground wave signal) (column 5 lines 1-4) and the output to intermediate frequency demodulation stage for ground wave, corresponding to the claimed first carrier of the multiple carriers);

Intel Ex. 1314 (Office Action) at 4;
Patent Owner Response, p. 25

1. (Currently amended) An apparatus comprising:

a first amplifier stage configured to receive and amplify an input radio frequency (RF) signal and provide a first output RF signal to a first load circuit when the first amplifier stage is enabled, the input RF signal employing carrier aggregation comprising transmissions sent on multiple carriers at different frequencies to a wireless device, the first output RF signal including at least a first carrier of the multiple carriers; and
a second amplifier stage configured to receive and amplify the input RF signal and provide a second output RF signal to a second load circuit when the second amplifier stage is enabled, the second output RF signal including at least a second carrier of the multiple carriers different than the first carrier.

Intel Ex. 1315 (Amendment) at 2;
Patent Owner Response, p. 25

Patent Owner Narrowed Claims to Overcome Hirose

Office Action alleges:

Hirose discloses ... receiving *input RF signal* (e.g. *satellite wave signal and ground wave signal*) (Office Action, p. 3; emphasis added)

Applicant respectfully asserts that Hirose's "satellite wave signal and ground wave signal" do not result in "carrier aggregation" as claimed by Applicant in amended independent claims 1 and 17. As stated, Applicant's amended independent claims 1 and 17 recite, *inter alia*, "the [] input RF signal employing *carrier aggregation*," while Hirose discloses *redundant* data at a *common* data rate. Specifically, Hirose discloses:

In an area where it is difficult to receive a radio wave from an elliptical orbit satellite or in an urban area where it is difficult to receive a satellite broadcast radio wave, a radio broadcast receiver receives in some cases a *radio wave (ground wave) from a ground repeater* which is controlled by a Geo stationary orbit satellite.

Therefore, the *satellite radio broadcast receiver receives three radio waves in total, two satellite waves and one ground wave, at the same time* at its wide band RF amplifier. FIG. 2 shows the spectrum of radio waves to be received by the receiver. The center frequency of this spectrum is approximately 2.3 GHz, and the satellite wave and ground wave have both the band width of about 4 MHz. Although the *satellite wave #1 and the ground wave are received at the same timing, the satellite wave #2 is received at the timing delayed by several seconds*, and so time diversity is presented

Intel Ex. 1315 (Amendment) at 8;
Patent Owner Response, p. 26

(21) Appl. No.: **13/590,423**

(22) Filed: **Aug. 21, 2012**

A wireless device may support carrier aggregation, which is simultaneous operation on multiple carriers. A carrier may refer to a range of frequencies used for communication and may be associated with certain characteristics. For example, a carrier may be associated with system information describing operation on the carrier. A carrier may also be referred to as a component carrier (CC), a frequency channel, a cell, etc. It is desirable to efficiently support carrier aggregation by the wireless device.

Wireless device 110 may support carrier aggregation, which is operation on multiple carriers. Carrier aggregation may also be referred to as multi-carrier operation. Wireless device 110 may be able to operate in low-band from 698 to 960 megahertz (MHz), mid-band from 1475 to 2170 MHz, and/or high-band from 2300 to 2690 and 3400 to 3800 MHz. Low-band, mid-band, and high-band refer to three groups of bands (or band groups), with each band group including a number of frequency bands (or simply, “bands”). Each band may cover up to 200 MHz and may include one or more carriers. Each carrier may cover up to 20 MHz in LTE. LTE Release 11 supports 35 bands, which are referred to as LTE/UMTS bands and are listed in 3GPP TS 36.101. Wireless device 110 may be configured with up to 5 carriers in one or two bands in LTE Release 11.

Long Term Evolution (LTE) Advanced is a mobile telecommunication standard proposed by the 3rd Generation Partnership Project (3GPP) and first standardised in 3GPP Release 10. In order to provide the peak bandwidth requirements of a 4th Generation system as defined by the International Telecommunication Union Radiocommunication (ITU-R) Sector, while maintaining compatibility with legacy mobile communication equipment, LTE Advanced proposes the aggregation of multiple carrier signals in order to provide a higher aggregate bandwidth than would be available if transmitting via a single carrier signal. This technique of Carrier Aggregation (CA) requires each utilised carrier signal to be demodulated at the receiver, whereafter the message data from each of the signals can be combined in order to reconstruct the original data. Carrier Aggregation can be used also in other radio communication protocols such as High Speed Packet Access (HSPA).

One technique for providing additional bandwidth capacity to wireless devices is through the use of carrier aggregation of multiple smaller bandwidths to form a virtual wideband channel at a wireless device (e.g., UE). In carrier aggregation (CA) multiple component carriers (CC) can be aggregated and jointly used for transmission to/from a single terminal. Carriers can be signals in permitted frequency domains onto which information is placed. The amount of information that can be placed on a carrier can be determined by the aggregated carrier's bandwidth in the frequency domain. The per-

Carrier aggregation (CA) enables multiple carrier signals to be simultaneously communicated between a user's wireless device and a node. Multiple different carriers can be used. In some instances, the carriers may be from different permitted frequency domains. Carrier aggregation provides a broader choice to the wireless devices, enabling more bandwidth to be obtained. The greater bandwidth can be used to communicate bandwidth intensive operations, such as streaming video or communicating large data files.

Qualcomm, Inc.

Strategies to win in LTE and evolve to LTE Advanced

September 2013

3.1 Carrier aggregation and its evolution

Carrier aggregation, as the name suggests, combines multiple carriers (a.k.a. channels) at the device to provide a bigger data pipe to the user. A bigger data pipe means higher data rates, both peak data rates (as high as over 1 Gbps) and, more importantly, higher user data rates across the cell coverage area. The higher data rates can be traded off to get increased capacity for bursty applications such as browsing, social media apps, smartphone usage and more.

As a first step, the commercial launch supported aggregation of two 10 MHz carriers, enabling a 150 Mbps peak data rate (Cat 4 terminals).

This also doubles the user data rates across the cell, whether the user is close to the cell or at the cell edge. As mentioned before, this higher data rate can also be traded off to provide twice (or more) the capacity for bursty apps, under typical loading conditions.

Carrier aggregation continues to evolve to utilize all spectrum resources that operators have access to. There could be aggregation across more carriers (up to five defined in LTE Advanced) and more band combinations (more than 45 being defined in 3GPP). There will be many different types

Fig. 3.2: LTE Advanced supports carrier aggregation of up to 5 carriers (100 MHz)

Publication Classification

[0003] Carrier aggregation provides an increase in data throughput capability by allowing different parts of the frequency spectrum to be combined logically to form a single channel (e.g. over-the-air interface between a base station and a user equipment). The technique of carrier aggregation thus allows an expansion of the effective bandwidth which can be utilized in wireless communication by concurrent utilization of radio resources across multiple carriers. Multiple component carriers are aggregated to form a larger overall transmission bandwidth. Carrier aggregation spreads the available signal power over a wider bandwidth, and greatly improves throughput for high-order modulation schemes.

Patentability

[0017] FIG. 1 is a diagram illustrating a first exemplary implementation of a signal amplification circuit according to the present invention. The exemplary signal amplification circuit 100 is for processing an input signal VIN to be received/transmitted. In other words, the signal amplification circuit 100 can be part of a receiver or part of a transmitter. For example, regarding signal reception, the input signal VIN may include a plurality of a radio-frequency signals (e.g., a Bluetooth signal and a WiFi signal) received by a single antenna (not shown), and a plurality of received signals corresponding to the radio-frequency signals are generated as outputs of the signal amplification circuit 100. Regarding

Lee is Unrelated to Carrier Aggregation

“Lee never describes the VIN signal (or anything else) as ‘employing carrier aggregation.’ Instead, Lee consistently refers throughout to two separate and distinct input signals ‘(e.g., a Bluetooth signal and a WiFi signal) received by a single antenna.’... In fact, Lee is clear that a key goal of his invention is to provide outputs of the WiFi and Bluetooth inputs that are kept separate.”

[0002] As people around the world embrace mobile lifestyles, there is a growing demand for their mobile devices to support several different kinds of radio connections. For example, a mobile device may have multiple wireless connections (e.g., a Bluetooth connection and a WiFi connection) at the same time. If transmitters/receivers for different radio connections are implemented in a multi-radio device individually, the hardware cost and the chip size may be high. Therefore, regarding a multi-radio device, there is a need for receiving/transmitting signals according to one input. For example, if a low-noise amplifier (LNA) of the multi-radio device can be configured to commonly amplify a plurality of radio-frequency signals, the LNA shared between different radio connections, such as the Bluetooth connection and the WiFi connection, would reduce the chip size of the multi-radio device. Therefore, the signal amplification circuit according to one input is designed by designers in this field.

impedance matching. In a case where the signal amplification circuit 100 serves as a low-noise amplifier in a receiver of a multi-radio device, the signal amplification circuit 100 is capable of supporting multiple radio connections such as a Bluetooth connection and a WiFi connection. Therefore, the

The Feasibility Study Relates to Single Radio Technology

Further Advancements

3rd Generation Partnership Project:

1 Scope

This document is related to the technical report for the study item "Further advancements for E-UTRA" [1].

This activity involves the Radio Access work area of the 3GPP studies and has impacts both on the Mobile Equipment and Access Network of the 3GPP systems.

This document is intended to gather all technical outcome of the study item, and draw a conclusion on way forward.

In addition this document includes the results of the work supporting the 3GPP submission of "LTE Release 10 & beyond (LTE-Advanced)" to the ITU-R as a candidate technology for the IMT-Advanced.

5.1 General

LTE-Advanced extends LTE Rel.-8 with support for *Carrier Aggregation*, where two or more *component carriers* (CCs) are aggregated in order to support wider transmission bandwidths up to 100MHz and for spectrum aggregation.

Petitioner Has Provided No Reasoned Motivation to Combine

possibly different bandwidths in the UL [uplink] and the DL [downlink].”). The Feasibility Study further suggests that an ideal receiver for noncontiguous intra-band and inter-band carrier aggregation¹⁹ would have multiple RF front-ends. *See id.* at 26 (describing “Option B” with “multiple” Rx architecture for non-contiguous carrier aggregation). The Feasibility Study characterizes an “RF front end” as having its own gain control (amplifier), mixer, and analog-to-digital conversion. *See id.* (“RF front end (i.e., mixer, AGC [Automatic Gain Control], ADC [Analog to Digital Conversion]”). Lee teaches multiple amplifier blocks providing output to different receivers. *See* EX1335-Lee ¶29. Lee thus teaches the exact type of receiver that the Feasibility Study recognizes would work with signals employing carrier aggregation. The motivation to combine Lee with the teachings of the Feasibility Study arises from the references themselves and requires nothing more than substitution of the “plurality of radio frequency signals” of Lee for the “Carrier Aggregation” signals described in the Feasibility Study. EX1302-Fay-Decl. ¶134.

Petitioner Has Provided No Reasoned Motivation to Combine

A POSITA would have been motivated to use the carrier aggregated input RF signal of the Feasibility Study with the amplification blocks of Lee. The Feasibility Study teaches that carrier aggregation may provide benefits, such as wider transmission bandwidths and spectrum aggregation. See EX1304-Study at 8. The Feasibility Study further teaches that carrier aggregation is supported by LTE-Advanced. *Id.* A POSITA would have been motivated to use the input RF signal employing carrier aggregation of the Feasibility Study with the amplification blocks of Lee in order to achieve these benefits and unlock the features of LTE-Advanced. EX1302-Fay-Decl. ¶135.

LOW NOISE AMPLIFIERS FOR CARRIER AGGREGATION

CLAIM OF PRIORITY UNDER 35 U.S.C. §119

The present Application for Patent claims priority to Provisional U.S. Application Ser. No. 61/652,064, entitled "LOW NOISE AMPLIFIERS FOR CARRIER AGGREGATION," filed May 25, 2012, assigned to the assignee hereof, and expressly incorporated herein by reference.

BACKGROUND

I. Field

The present disclosure relates generally to electronics, and more specifically to low noise amplifiers (LNAs).

Patent Owner Response, p. 41

Patent Owner Sur-Reply, p. 22-24

Intel Ex. 1301, 1:16-17

The Feasibility Study is Non-Analogous Art

3GPP TR 36.912 V9.1.0 (2009-12)

Technical Report

11.3.3.1 Receiver architecture

Table 11.3.3-1 illustrates various Rx architectures options for the three scenarios

Table 11.3.3.1-1: Possible UE Architecture for the three aggregation scenarios

Option	Description (Rx architecture)	Rx Characteristics		
		Intra Band aggregation		Inter Band aggregation
		Contiguous (CC)	Non contiguous (CC)	Non contiguous (CC)
A	Single (RF + FFT + baseband) with BW>20MHz	Yes		
B	Multiple (RF + FFT + baseband) with BW≤20MHz	Yes	Yes	Yes

Option A

- UE may adopt a single wideband-capable (i.e., >20MHz) RF front end (i.e., mixer, AGC, ADC) and a single FFT, or alternatively multiple "legacy" RF front ends (≤20MHz) and FFT engines. The choice between single or multiple transceivers comes down to the comparison of power consumption, cost, size, and flexibility to support other aggregation types.

Option B

- In this case, using a single wideband-capable RF front end is undesirable in the case of Intra band non contiguous CC due to the unknown nature of the signal on the "unusable" portion of the band. In the case non adjacent Inter band separate RF front end are necessary.

- 4) Petitioner Relies Improperly on Two Different Lee Embodiments for Claim 7

'356 Patent – Claim 7

1. An apparatus comprising:

a first amplifier stage configured to be independently enabled or disabled, the first amplifier stage further configured to receive and amplify an input radio frequency (RF) signal and provide a first output RF signal to a first load circuit when the first amplifier stage is enabled, the input RF signal employing carrier aggregation comprising transmissions sent on multiple carriers at different frequencies to a wireless device, the first output RF signal including at least a first carrier of the multiple carriers; and

a second amplifier stage configured to be independently enabled or disabled, the second amplifier stage further configured to receive and amplify the input RF signal and provide a second output RF signal to a second load circuit when the second amplifier stage is enabled, the second output RF signal including at least a second carrier of the multiple carriers different than the first carrier.

7. The apparatus of claim 1, further comprising:

a feedback circuit coupled between an output and an input of at least one of the first and second amplifier stages.

FIG. 7

Petitioner Relies Improperly on Two Separate Lee Embodiments for Claim 7

Claims 1[a] and 1[b]: *“An apparatus comprising a first amplifier stage configured to be independently enabled or disabled”*: As illustrated in the annotated Lee Figure 4, below, Lee discloses an apparatus (e.g., amplification circuit 400) comprising a first amplifier stage (e.g., transistor M’_1 and output stage 304_1, shown in red below). EX1335-Lee ¶¶34, 35, 38, Fig. 4. This first amplifier stage is configured to be independently enabled or disabled. EX1335-

Lee ¶37 (“When only the WiFi function of the multi-radio device is required to be active, the output stage 304_1 is enabled, whereas the remaining output stages in the signal amplification circuit . . . are disabled. . . . Similarly, when only the Bluetooth function of the multi-radio device is required to be active, the output stage 304_N is turned on, whereas the remaining output stages in the signal amplification circuit . . . are disabled.”). Amplification circuit 400 may also operate in combo mode, in which both stages are enabled. See EX1335-Lee ¶¶41-42, 33; EX1302-Fay-Decl. ¶92.

Petitioner Relies Improperly on Two Separate Lee Embodiments for Claim 7

[0036] In addition to setting the gain applied to a signal passing therethrough, each of the output stages 304_1-304_N is arranged to further control if a processed signal is allowed to be generated at a corresponding output port, and therefore control whether the output stage should be enabled. That is, the output stages 304_1-304_N also control the operation of the signal amplification circuit 100 under the shared mode. More specifically, a plurality of specific output stages included in the output stages 304_1-304_N are enabled in a time-division manner. Taking the output stage 304_1 for

[0037]

requirements. If the output stages 304_1 and 304_N are enabled alternately under the mode, the signal amplification circuit 300 refers to the input signal VIN to generate the processed signal VOUT_1 for WiFi connection and the other processed signal VOUT_N for Bluetooth connection alternately.

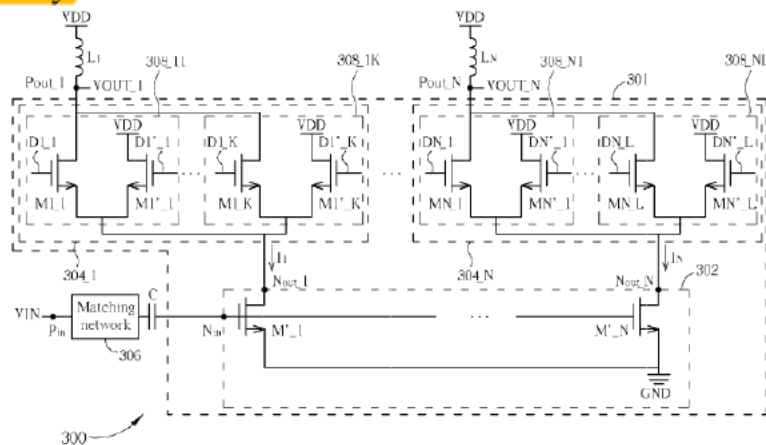

FIG. 3

[0041] As mentioned above, each of the feedback elements 402_1-402_N can be properly designed to adjust the input matching. In an alternative design, the signal amplification circuit 400 shown in FIG. 4 may operate under a combo mode due to the implemented feedback elements 402_1-402_N. For example, the input matching is constant no matter how many output stages are enabled concurrently. In this way, the signal amplification circuit 400 has a low noise figure.

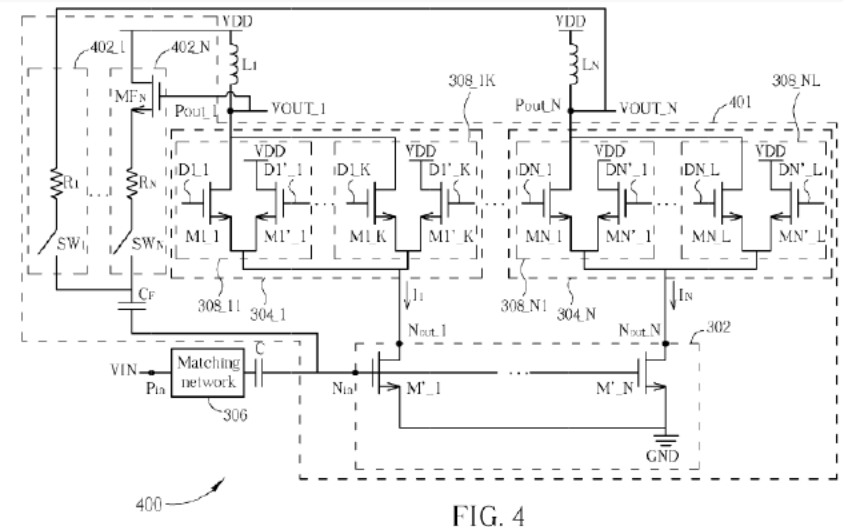

FIG. 4
