(54) Title: SYSTEM FOR AND METHOD OF DISTRIBUTING TELEVISION, VIDEO AND OTHER SIGNALS

(57) Abstract: A system for distributing television/video signals to different locations comprises a server capable of providing digital television/video signals for a plurality of programmes, a plurality of receivers each at a respective one of said locations, and a network connecting the server to the receivers, each receiver being operable to select a required one of the programmes and to communicate the selection to the server, the server being responsive to such a selection to transmit the digital television/video signal for the selected programme over the network addressed to the receiver that selected that programme, and each receiver being responsive to the digital television/video signal that is addressed to that receiver so that point-to-point communication is established from the server to that receiver.

## SYSTEM FOR AND METHOD OF DISTRIBUTING TELEVISION, VIDEO AND OTHER SIGNALS

5           This invention relates to distribution and networking of television, video and other signals, installation of such distribution systems, and control of television sets.

          Certain aspects of this invention find particular application in a media distribution/networking system for use in a hotel. It will be understood, however, that the invention can also be applied to other distribution/networking systems. Likewise, as  
10       used herein, the term "hotel" is preferably to be understood as encompassing any form of establishment where guests are temporarily allocated a room or similar or part thereof, whether for payment or not.

          In a traditional hotel media distribution system, different media services, such as television programmes, radio programmes and movies are broadcast around the hotel  
15       using a distribution network of coaxial cable. Each service is provided on the coaxial cable as an analogue signal with a different channel frequency, and the receiving equipment (such as a television) in each hotel room can be tuned to the required channel to receive the desired service.

          Similarly, in the cable distribution of television signals to dwellings in a  
20       neighbourhood ("cable television"), each programme is provided on the cable as a signal with a different channel frequency, and the receiving equipment in each dwelling can be tuned to the required channel to receive the desired programme.

          Low-grade coaxial cable (such as RG59 cable) that has traditionally been used in hotel distribution networks has a typical bandwidth of 460 MHz. An analogue television  
25       signal occupies a bandwidth of 6 MHz. There is therefore a limit of about seventy-six channels that can be used in such a system. There is a desire to increase the range of services that are available to each hotel room or dwelling and to facilitate the provision of room-specific or dwelling-specific services.

In the following, references are made to a server, a receiver, a network, a conductor, a 2-way amplifier, a first circuit board, and a second circuit board. Such a server may alternatively be replaced by a means for providing signals, preferably digital television/video signals; such a receiver may alternatively be replaced by a means for receiving signals, preferably digital television/video signals; such a network may alternatively be replaced by a means for connecting a server to receivers, or for connecting the providing means to the receiving means; such a conductor may alternatively be replaced by a means for carrying a plurality of signals; such a 2-way amplifier may alternatively be replaced by a means for amplifying/maintaining the signal level of signals; such a first circuit board may alternatively be replaced by a first control means; and such a second circuit board may alternatively be replaced by a second control means.

One aspect of the invention provides a system for distributing television/video signals to different locations (such as different rooms in a hotel, or different dwellings in a neighbourhood), the system comprising a server capable of providing digital television/video signals for a plurality of programmes, a plurality of receivers each at a respective one of said locations, and a network connecting the server to the receivers, each receiver being operable to select a required one of the programmes and to communicate the selection to the server, the server being responsive to such a selection to transmit the digital television/video signal for the selected programme over the network addressed to the receiver that selected that programme, and each receiver being responsive to the digital television/video signal that is addressed to that receiver so that point-to-point communication is established from the server to that receiver.

By providing the services by way of digital, rather than analogue, signals, and using a digital point-to-point network (for example using a switched internet protocol (IP)) between one or more servers and the receivers, the modern requirements for such a system can more easily be met.

A bandwidth to each receiver of 10 Mbps is sufficient for video, and therefore in one embodiment of the invention a substantial part of a cable run of the network from the server to the receivers may be provided by data grade twisted-pair cable, such as twisted-pair cable that substantially complies with or exceeds the specification of

ANSI/EIA/TIA-568-1991, Category 3, and more preferably complies with or exceeds the specification of Category 5, i.e. that type of cable currently normally used for 10baseT or 100baseTX computer networks.

5 The installation of such cabling and any necessary switches in a new hotel would not cause a problem. However, the installation of such cabling into an existing hotel may in many instances be difficult, expensive and inconvenient. Nevertheless, most hotels have a telephone system, with a telephone in each room. Telephone-grade twisted pair cabling is not designed for use in a television/video network and is of inferior quality to standard network cable (Category 5), but it has been realised that it can be used for the  
10 transmission of digital television/video signals in a controlled environment such as a hotel.

Accordingly, in another embodiment of the invention, a substantial part of a cable run of the network from the server to the receivers is provided by telephone-grade twisted-pair cable.

15 Features which distinguish conventional telephone-grade twisted-pair cable from standard network cable are:

- it falls below the specification of ANSI/EIA/TIA-568-1991, Category 3;
- it may be in accordance with British Telecommunications specification CW1308;
- 20 • it may be of the type known as Category 2 twisted-pair (even though category 2 is no longer a standard specified by ANSI/EIA/TIA);
- it has a characteristic impedance at 16 MHz substantially higher than 115  $\Omega$ ; and/or
- for a run to a single telephone, it has less than four twisted pairs.

25

Preferably, the system further includes a telephone connected by a first splitter to the network, in particular to the telephone grade cable, adjacent the respective receiver, and a telephone exchange connected by a second splitter to the network, in particular to the telephone grade cable, remote from the respective receiver. Accordingly, an existing  
30 telephone system can continue to be used.

Another aspect of the invention provides a receiver for use in a system for distributing television/video signals to different locations, the system comprising a server capable of providing digital television/video signals for a plurality of programmes, and the receiver comprising means for enabling connection to the server by  
5 means of a network (for example, a connector, for instance a telephone or coaxial connector), means for selecting a required one of the programmes (for example a keypad), and means for communicating the selection to the server (for example, a transmitter), the receiver being responsive to a digital television/video signal that is transmitted by the server over the network and addressed to that receiver so that point-  
10 to-point communication is established from the server to that receiver, and preferably, the receiver is tuned to a given channel.

Preferably, the receiver further comprises means for converting the digital signals to analogue signals (for instance an analogue to digital processor) for supply to a  
15 picture/sound reproduction means (for example a visual display unit, for example a television), and the digital to analogue converting means may include means for decompressing the digital signals (for example using decompression techniques such as MP3 or MPEG2 decompression techniques).

20 Another aspect of the invention provides a receiver for use in a system for distributing television/video signals to different locations, the system comprising a server capable of providing digital television/video signals for a plurality of programmes, the receiver comprising a connection to the server via a network, a selector for selecting a required one of the programmes, and a transmitter for communicating the  
25 selection to the server, the receiver being responsive to a digital television/video signal that is transmitted by the server over the network and addressed to that receiver so that point-to-point communication is established from the server to that receiver.

Another aspect of the invention provides a method of installing such a  
30 distribution system for premises having an existing arrangement of telephone cable for a telephone system of the premises, the method including using at least part of the existing arrangement of telephone cable in the network of the distribution system.

As mentioned above, the installation of new Category 5 cabling into an existing hotel may in many instances be difficult, expensive and inconvenient. However, most hotels have an existing coaxial cable network for distributing analogue television signals. Conventional analogue television coaxial cable is of inferior quality, but it has  
5 been realised that it can be used for the transmission of digital television/video signals in a controlled environment such as a hotel.

Accordingly, in a further embodiment of the invention, a substantial part of a cable run of the network from the server to the receivers is provided by a conductor, preferably coaxial cable, arranged to carry the digital television/video signals for those  
10 receivers, those signals being provided on respective channels each allocated to a respective one of the receivers, and each receiver being tuned to its respective channel.

As mentioned above, RG59 coaxial cable places a limit of about seventy-six on the number of channels and therefore on the number of programmes that it can carry in a conventional arrangement. However, with this embodiment of the invention, there is no  
15 limit that the cable places on the number of programmes or other services that the server can make available, because each channel is associated with a particular receiver, rather than a particular programme. There is a limit on the number of receivers that can be connected to the cable if each receiver is to have its own channel, but in the context of hotel distribution, or neighbourhood cable television distribution, this limit is not a  
20 problem.

Especially in a hotel environment, the coaxial cable may be analogue television grade coaxial cable, because it is relatively inexpensive and may already be installed. Features which distinguish such cable from, for example, the coaxial cable which is used in 10Base2 computer networks are that:

- 25 • it has a characteristic impedance of 75  $\Omega$ , as opposed to 50  $\Omega$ ; and/or
- it is substantially in accordance with specification RG59 or RG62.

Preferably, each of the plurality of receivers is connected to the coaxial cable via a cable modem whose tuning is preset to the channel allocated to the respective receiver. Also, the server is preferably connected to the coaxial cable via a cable modem that is  
30 controlled by the server to place the digital television/video signal for the programme

selected for each receiver on the channel allocated to that receiver.

Another aspect of the invention provides a method of installing such a distribution system for premises having an existing arrangement of coaxial cable for distributing analogue television signals in or to the premises, the method including the  
5 step of using at least part of the existing arrangement of coaxial cable in the network of the distribution system.

A further aspect of the invention provides a corresponding method of distributing television/video signals to different locations, the method comprising providing a server capable of providing digital television/video signals for a plurality of programmes,  
10 providing a plurality of receivers each at a respective one of said locations, providing a network connecting the server to the receivers, each receiver selecting a required one of the programmes and communicating the selection to the server, the server responding to such a selection and transmitting the digital television/video signal for the selected programme over the network addressed to the receiver that selected that programme, and  
15 each receiver responding to the digital television/video signal that is addressed to that receiver so that point-to-point communication is established from the server to that receiver. Preferably, the transmitting includes transmitting the digital television/video signal over telephone-grade twisted-pair cable and/or transmitting the digital television/video signal over coaxial cable on a channel allocated according to the  
20 receiver to which the signal is being sent, and each receiver being tuned to its respective channel.

It should be noted that the channel allocation feature described above in relation to transmission of digital television/video signals over coaxial cable provides similar advantages when applied to the transmission of other signals over other conductors.  
25 Accordingly, another aspect of the invention provides a networked system comprising a server and a plurality of devices connected to the server by a network, at least part of the network being provided by a conductor for carrying a plurality of signals between the server and the devices, the signals being multiplexed on the conductor each on a preset channel allocated according to the device so that each device has a respective preset one  
30 of the channels. The signals may be digital signals. Preferably, the signals are frequency-multiplexed and/or phase-multiplexed on the conductor. The conductor may

be an electrical conductor, such as coaxial cable with the features mentioned above, and the signals may be electrical signals, or the signals may be optical signals and the conductor may be an optical conductor.

It should be noted that in systems where channels are allocated on a per service basis, rather than on a per device or per user basis, if two-way communication is to be provided, at least one further channel needs to be provided for signals from the devices or users to the server. However, in the case of the invention, if the network provides two-way communication between the server and each terminal, the same channel may be used for communication from the server to a particular one of the devices as for communication from that device to the server. Communication from one of the devices to the server will not interfere with communication from the server to the other devices.

A further aspect of the invention provides a networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective connector address, the system comprising a memory for storing the device addresses and, for each device address, a corresponding connector address, and a processor for comparing, for a given device address, whether the stored corresponding connector address matches the connector address of the second connector part adjacent the device, the system being arranged to perform different processes depending on the result of the comparison.

Another aspect of the invention provides a networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective connector address, the system comprising a memory for storing the device addresses and, for each device address, a corresponding connector address, and a processor for comparing, for a given second connector part, whether the stored corresponding device address matches the device address of the device adjacent the second connector part, the system being arranged to

perform different processes depending on the result of the comparison.

Another aspect of the invention provides a corresponding method of operation of a networked system comprising a server and a plurality of devices at different locations connected to the server by a network, at least part of the network being provided by a conductor for carrying a plurality of signals between the server and the devices, the  
5 method including the step of multiplexing the signals on the conductor each on a preset channel allocated according to the device so that each device has a respective preset one of the channels.

A further aspect of the invention provides a method of operation of a networked  
10 system comprising a server and a plurality of devices at different locations connected to the server by a network, at least part of the network being provided by coaxial cable having at least one branch which is divided at a node into at least two sub-branches in a path direction extending away from the server, and a two-way amplifier being provided at the node to amplify/maintain the signal level of signals passing from the sub-branches  
15 to the branch in addition to the signal level of signals travelling from the branch to the sub-branches, the method comprising the step of transmitting a signal from at least one of the devices to the server generally at the same time as transmitting a signal from the server to the devices.

Although it is known to use two-way amplifiers in coaxial distribution systems,  
20 they are employed to facilitate relocation of the server rather than for generally simultaneous amplification of signals in the two directions.

Another aspect of the invention provides a method of operation of a networked system comprising a server and a plurality of devices at different locations connected to the server by a network, at least part of the network being provided by coaxial cable  
25 having at least one branch which is divided at a node into at least two sub-branches in a path direction extending away from the server, and a two-way amplifier being provided at the node to amplify/maintain the signal level of signals passing from the sub-branches to the branch in addition to the signal level of signals travelling from the branch to the sub-branches, the method comprising transmitting the signals from the server to the  
30 devices on different channels allocated according to the device, and transmitting signals

from each device to the server on the same channel as is used for transmission from the server to that device.

Again, although it is known to use two-way amplifiers in coaxial distribution systems, they are not employed in the case where channels are allocated on a per device  
5 or per user basis.

It will be appreciated that a particular system can advantageously employ one or both of the latter two aspects of the invention.

A further aspect of the invention provides a networked system comprising a server and a plurality of devices at different locations connected to the server by a  
10 network, at least part of the network being provided by coaxial cable having at least one branch which is divided at a node into at least two sub-branches in a path direction extending away from the server, and a two-way amplifier being provided at the node to amplify/maintain the signal level of signals passing from the sub-branches to the branch in addition to the signal level of signals travelling from the branch to the sub-branches,  
15 the system being operable to transmit a signal from at least one of the devices to the server generally at the same time as a signal is transmitted from the server to the devices.

A further aspect of the invention provides a networked system comprising a server and a plurality of devices at different locations connected to the server by a network, at least part of the network being provided by coaxial cable having at least one  
20 branch which is divided at a node into at least two sub-branches in a path direction extending away from the server, and a two-way amplifier being provided at the node to amplify/maintain the signal level of signals passing from the sub-branches to the branch in addition to the signal level of signals travelling from the branch to the sub-branches, the system being arranged to transmit the signals from the server to the devices on  
25 different channels allocated according to the device, and to transmit signals from each device to the server on the same channel as is used for transmission from the server to that device.

A further aspect of the invention provides a system for distributing television/video/radio/audio signals to different locations, the system comprising means

for receiving analogue television or radio signals or for generating analogue video or audio signals (for instance a reception and production centre, comprising for instance a central receiver, or a production suite), means for converting the analogue signals to digital signals (for instance an analogue to digital processor) and supplying the digital  
5 signals to a server, a plurality of receivers each at a respective one of said locations, and a network connecting the server to the receivers, each receiver including means for converting the digital signals to analogue signals (for instance, a digital to analogue processor) for supply to a picture/sound reproduction means (for example a visual display unit, for example a television).

10 Therefore, although digital networking is employed with its associated advantages, the source signals may be analogue signals and the output signal may be used by a picture/sound reproduction means (for instance a visual display unit such as a television) with a conventional analogue input.

The analogue to digital converting means preferably includes means for  
15 compressing the digital signals to a standard compressed digital format (for instance a processor, in particular a processor adapted to operate MPEG2 or MP3 compression routines), and each digital to analogue converting means preferably includes means for decompressing the digital signals. This reduces the amount of network traffic.

The receiving means may include an aerial for receiving modulated terrestrial  
20 analogue television/radio signals for a plurality of programmes, and means for demodulating the modulated signal for at least one of the programmes (for example a processor).

Additionally or alternatively, the receiving means may include a satellite dish for receiving scrambled and multiplexed satellite analogue television signals for a plurality  
25 of programmes, and means for descrambling and demultiplexing the signal for at least one of the programmes (for example a processor). However, since many satellite distributors use proprietary software and hardware (their "set top box") to ensure that programmes are only received by registered subscribers, the receiving means may alternatively or additionally include a satellite receiver, for instance a satellite dish, for  
30 receiving scrambled and multiplexed satellite analogue television signals for a plurality

of programmes, means for descrambling and demultiplexing the signal for at least one of the programmes to produce an intermediate signal, means for modulating an RF signal with the intermediate signal, and means for demodulating the modulated RF signal. The descrambling, demultiplexing and modulating may therefore be provided by a  
5 conventional set top box.

Another aspect of the invention provide a system for distributing television/video/radio/audio signals to different locations, the system comprising a reception and production centre for receiving analogue television or radio signals or for generating analogue video or audio signals, a processor for converting the analogue  
10 signals to digital signals and supplying the digital signals to a server, a plurality of receivers each at a respective one of said locations, and a network connecting the server to the receivers, each receiver including a digital to analogue convertor for converting the digital signals to analogue signals for supply to an output device.

15 Another aspect of the invention provides a corresponding method of distributing television/video/radio/audio signals to different locations, comprising: receiving analogue television or radio signals or generating analogue video or audio signals, converting the analogue signals to digital signals, supplying the digital signals to a server, distributing the digital signals over a network to a plurality of receivers each at a  
20 respective one of said locations, and, at each receiver, converting the digital signal to an analogue signal and reproducing a picture/sound from the analogue signal.

The various systems and methods mentioned above are particularly applicable in the case where the different locations are different rooms in a hotel.

In a conventional hotel television distribution system using analogue signals on  
25 coaxial cable, the coaxial cable can be connected directly to the aerial input of a conventional television set. With the distribution systems of the invention as described above, if a television set with an analogue input, such as an RGB, CVBS or S/VHS input, is to be used, a decoder also needs to be used. Also, nowadays, many television sets have the ability to be controlled via a control interface, and this can be used to  
30 advantage, for example so that the server can turn on the television and display the time for an alarm call or welcome message for a hotel guest. However, an industry standard

for such a control interface does not yet exist.

A further aspect of the invention provides a control system for a television set, comprising a first circuit on at least one first circuit board for receiving a digital video signal from a network and for decoding the digital video signal to produce a decoded  
5 video signal for supply to a standard video interface of the television set, the first circuit also being operable to receive control instructions from the network and/or from a user interface and to generate a generic control signal therefrom, the control system further comprising a second circuit provided on at least one second circuit board that is specific to the type of the television set, the second circuit being operable to receive the generic  
10 control signal from the first circuit and to convert the generic control signal into a specific control signal for supply to a control interface of the television set so as to control the television set in accordance with the control instructions.

Accordingly, the only part of the control system that needs to be specific to the  
15 particular television set is the second circuit board, and a single design can be employed for the first circuit board, whatever the type of television with which it is to be used.

In one embodiment, the second circuit board is installed in a slot on a main circuit board of the television set inside the housing of the television set, and the first circuit board is installed inside a housing distinct from the television set housing. In  
20 another embodiment, the first circuit board and the second circuit board are installed in first and second slots, respectively, on a main circuit board of the television set inside the housing of the television set. In a further embodiment, the second circuit board is installed in a first slot on a main circuit board of the television set inside the housing of the television set, and the first circuit board is installed in a second slot on the second  
25 circuit board or one of the second circuit boards.

A further aspect of the invention provides a combination of a first circuit on at least one first circuit board and a second circuit on at least one second circuit board for controlling a television set, the first circuit having means for receiving a digital video  
30 signal from a network (for example a receiver) and for decoding the digital video signal to produce a decoded video signal for supply to a standard video interface of the

television set, the first circuit further comprising means for receiving control instructions from the network and/or from a user interface and for generating a generic control signal (for example a processor) therefrom, the second circuit having means (for example, a processor) for receiving the generic control signal from the first circuit and for  
5 converting the generic control signal into a specific control signal having a different format than the generic control signal, for supply to a control interface of a television set so as to control the television set in accordance with the control instructions.

Preferably, both the first circuit board and the second circuit board have means  
10 for installation in respective first and second slots on a main circuit board of the television set. Preferably, the second circuit board has means (for example a connector) for installation in a first slot on a main circuit board of the television set, and the first circuit board has means (for example a connector) for installation in a second slot on the first circuit board or one of the first circuit boards.

15

A further aspect of the invention provides a combination of a first circuit on at least one first circuit board and a second circuit on at least one second circuit board for controlling a television set, the first circuit having a first receiver for receiving a digital video signal from a network and for decoding the digital video signal to produce a  
20 decoded video signal for supply to a standard video interface of the television set, the first circuit further comprising a processor for receiving control instructions from the network and/or from a user interface and for generating a generic control signal therefrom, the second circuit having a second receiver for receiving the generic control signal from the first circuit and for converting the generic control signal into a specific  
25 control signal having a different format than the generic control signal, for supply to a control interface of a television set so as to control the television set in accordance with the control instructions.

The invention further provides a range of circuit boards for controlling a  
30 television set, each circuit board of the range comprising means for connection to a generic circuit board, each circuit board of the range comprising means (for example, a receiver) for receiving a generic control signal, based on control instructions received from a network and/or from a user interface, from the generic circuit board, and means

(for example a processor) for converting the generic control signal into a specific control signal having a different format than the generic control signal, and means (for example a transmitter) for supplying the specific control signals to a control interface of the television set so as to control the television set in accordance with the control instructions.

Preferably, the formats of the specific control signals are all different for different control boards of the range. Preferably, each circuit board of the range has a slot for installation of the generic circuit board therein.

Another aspect of the invention provides a range of circuit boards for controlling a television set, each circuit board of the range comprising a connection to a generic circuit board, each circuit board of the range comprising a receiver for receiving a generic control signal, based on control instructions received from a network and/or from a user interface, from the generic circuit board, and a processor for converting the generic control signal into a specific control signal having a different format than the generic control signal, and for supplying the specific control signals to a control interface of the television set so as to control the television set in accordance with the control instructions.

Another aspect of the invention provides a method of configuring such a control system for a particular television set, the method comprising selecting, from a collection of such second circuit boards for different types of television sets, a circuit board that is specific to the type of the particular television set, and installing the selected second circuit board in conjunction with such a first circuit board.

In the case where a control system such as described above is movable, there is a problem especially in a hotel environment that a guest may take the control system from another (hotel) room to use in their own (hotel) room, for example because the control system in their own (hotel) room is not functioning properly, or so as to obtain programmes or other services to which they are not entitled or for which they wish to avoid paying. As a result, the other room is left without a control system and/or the hotel may lose revenue.

An attempt to deal with a related problem is described in patent document US-A-5455619. Each control system is connected to the network by a wall box which includes an address tag, and the control system reads the address of the address tag when it is powered up, stores it in non-volatile memory and supplies it to the server. If the address  
5 which is read when the control system is subsequently powered up is different, it is assumed that the control system and guest have moved to a new room, and so the guest continues to be billed for the service provided in the new room. The system is therefore geared to keeping track of the authorised movement of such control systems from one room to another.

10 To deal with the problem of unauthorised movement of a device from one place to another, another aspect of the invention provides a networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the  
15 remainder of the network, each device having a respective device address, each second connector part having a respective connector address, the server storing the device addresses and, for each device address a corresponding connector address, and each device being operable to:- (a) supply its device address to the server and request the corresponding connector address, (b) receive the corresponding connector address from  
20 the server, (c) request the connector address from the respective connector, (d) receive the connector address from the connector, (e) compare the connector addresses received from the server and the connector, and (f) perform different processes in dependence upon whether or not the compared addresses match.

Preferably, each device is operable to (a) supply its device address to the server  
25 and request the corresponding connector address, (b) receive the corresponding connector address from the server, (c) request the connector address from the respective connector, (d) receive the connector address from the connector, (e) compare the connector addresses received from the server and the connector, and (f) perform different processes in dependence upon whether or not the compared addresses match,  
30 upon powering-up of the device, and, for example, if the compared addresses do match, to power-up to a fully-operational state, and, if the compared addresses do not match, to

power-up to a partly-operational state, or "safe mode". Each device is preferably also operable, if the compared addresses do not match, to notify the server that the compared addresses do not match.

Another aspect of the invention provides a networked system comprising a  
5 server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective connector address, the system comprising means (such as a memory, for example a solid state storage device) for  
10 storing the device addresses and, for each device address, a corresponding connector address, and means (for example a processor) for comparing, for a given device address, whether the stored corresponding connector address matches the connector address of the second connector part adjacent the device, the system being arranged to perform different processes depending on the result of the comparison. Preferably the comparing  
15 means forms part of the server.

A further aspect of the invention provides a networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part  
20 connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective connector address, the system comprising means (such as a memory, for example a solid state memory device) for storing the device addresses and, for each device address, a corresponding connector address, and means (such as a processor) for comparing, for a given second connector  
25 part, whether the stored corresponding device address matches the device address of the device adjacent the second connector part, the system being arranged to perform different processes depending on the result of the comparison. Preferably the comparing means forms part of the server.

30 Another aspect of the invention provides a corresponding method of operation of a device in a networked system comprising a server and a plurality of such devices

connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective device address, each second connector part having a respective connector address, and the server storing the device addresses and, for each device address a corresponding connector address, the method comprising (a) the device supplying its device address to the server and requesting the corresponding connector address, (b) the device receiving the corresponding connector address from the server, (c) the device requesting the connector address from the respective connector, (d) the device receiving the connector address from the connector, (e) the device comparing the connector addresses received from the server and the connector, and (f) the device performing different processes in dependence upon whether or not the compared addresses match.

In a further aspect the invention provides a method of operation of a networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective connector address, the method comprising (a) storing pairs of addresses, wherein each pair comprises a device address and a corresponding connector address, (b) comparing, for a given device address, whether the stored corresponding connector address matches the connector address of the second connector part adjacent the device, and (c) performing different processes depending on the result of the comparison.

In a further aspect, the invention provides a method of operation of a networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective device address, the method comprising (a) storing pairs of addresses, wherein each pair comprises a device address and a corresponding connector address, (b) comparing, for a given second connector part, whether the stored corresponding device address matches

the device address of the device adjacent the second connector part, and (c) performing different processes depending on the result of the comparison.

Preferably, with regard to the latter two aspects of the invention, the addresses are  
5 compared by the server.

Preferably, the device comprises means (for example a power-up controller) for performing said (a) to (c) upon powering-up, and the device has means (for instance a power control circuit) for powering-up to a fully-operational state if the compared  
10 addresses do match. Preferably, the device may have means (for instance a power control circuit) for powering-up to a partly-operational state if the compared addresses do not match. Further, the device preferably has means (such as an output device) for notifying the server that the compared addresses do not match if the compared addresses do not match.

15

In a further aspect, the invention provides a device for use in a networked system comprising a server and a plurality of such devices connectable to the server by a network via respective connectors, the device having a respective device address, the device comprising (a) means (such as an output device) for supplying its device address  
20 to the server and requesting a corresponding connector address stored in the server, (b) means (such as a receiver) for receiving the corresponding connector address from the server, (c) means (such as an output device) for requesting the connector address from a connector for the device, (d) means (such as a receiver) for receiving the connector address from the respective connector, (e) means (such as a processor, for example a  
25 comparator) for comparing the connector addresses received from the server and the connector, and (f) means (for example a processor) for performing different processes in dependence upon whether or not the compared addresses match.

Preferably, the device comprises means for performing the functionality of the elements (a) to (f) upon powering up.

30 In a further aspect the invention provides a device for use in a networked system comprising a server and a plurality of such devices connectable to the server by a

network via respective connectors, the device having a respective device address, the device comprising (a) an transmitter for supplying its device address to the server and requesting a corresponding connector address stored in the server, (b) a receiver for receiving the corresponding connector address from the server, (c) an output device for requesting the connector address from a connector for the device, (d) an input device for receiving the connector address from the respective connector, (e) a comparator for comparing the connector addresses received from the server and the connector, and (f) a processor for performing different processes in dependence upon whether or not the compared addresses match.

10 Features of any aspect of the invention may be combined with or interchanged with features of any other aspect as desired. Method features may be applied to apparatus aspects and *vice versa*. Features which are provided independently may be provided dependently, and *vice versa*.

Preferred embodiments of the invention will now be described, purely by way of example, with reference to the accompanying drawings in which:

- Figure 1 is a block diagram of a hotel with a conventional television signal distribution system;
- Figure 2 is a schematic diagram illustrating how various input signals are combined in the system of Figure 1;
- 20 Figure 3 is a schematic diagram illustrating tuning of a television to a particular one of the signals in the system of Figure 1;
- Figure 4 is block diagram of the hotel with a distribution system of one embodiment of the invention;
- Figure 5 is a block diagram of the hotel with a distribution system of another embodiment of the invention;
- 25 Figure 6 is a schematic diagram illustrating how various input signals are combined in the system of Figure 5;

- Figure 7 is a schematic diagram illustrating tuning of a television to a particular one of the signals in the system of Figure 5;
- Figure 8 is a drawing to illustrate a 64QAM modulation scheme;
- Figure 9 is a block diagram of the hotel with a conventional telephone system;
- 5 Figure 10 is block diagram of the hotel with a distribution system of a further embodiment of the invention;
- Figure 11 is a block diagram of equipment in a room of the hotel of Figure 10;
- Figure 12 is a more detailed block diagram of part of the equipment of the system of Figure 3, 4 or 10;
- 10 Figure 13 is a schematic rear view of a television and local control unit, with their rear covers removed, which may be used in the system of Figures 3, 4 or 10;
- Figure 14 is a schematic rear view of a combined television and local control unit, with its rear cover removed, which may be used in the system of Figures
- 15 3, 4 or 10;
- Figure 15A is a schematic rear view of a different combined television and local control unit, with its rear cover removed, which may be used in the system of Figures 3, 4 or 10;
- Figure 15B is similar to Figure 15A, but showing a modification;
- 20 Figure 16 is a block diagram of a local control unit together with a wall box connector;
- Figure 17 is a flow diagram of a boot process of a local control unit;
- Figure 18 is a block diagram of a server in the systems of Figures 4, 5 and 10; and
- Figures 19-23 are more detailed block diagrams of various parts of the server of Figure
- 25 18.

Referring to Figure 1, a conventional hotel 10 has a plurality of guest rooms 12, nine of which are shown in the drawing, each provided with a television set 14. The hotel 10 also has an equipment room 16 which is fed with analogue terrestrial television signals from an aerial 18 via an RG59 coaxial download 20 and also with digital satellite television signals from a satellite dish 22 via an FT125 coaxial cable download 24. The satellite television download 24 is connected to the input of at least one satellite television decoder (or "set top box") 26, which supplies analogue television signals for different programmes (say "SAT1", "SAT2" and "SAT3") on different frequency-multiplexed channels (say channels 1, 2 and 3) on an RG59 coaxial cable 28. The analogue terrestrial television signals provided by the download 20 contain different programmes (say "TERR1", "TERR2" and "TERR3") on the different frequency-multiplexed channels (say channels 4, 5 and 6) on which those signals were broadcast. The equipment room 16 also contains video replay equipment 30, such as a video tape player or DVD player, which provides analogue video signals for different programmes (say "VID1", "VID2" and "VID3") on further different frequency-multiplexed channels (say channels 7, 8 and 9) on a further RG59 coaxial cable 32. The coaxial cables 20, 28, 32 are connected to the inputs of a combiner 34, which provides a frequency-multiplexed output 36 having all nine programmes on their nine channels 1 to 9, as illustrated schematically by Figure 2. The output 36 of the combiner 34 is connected to the aerial inputs 46 of all of the televisions 14 by an RG59 distribution network 38 comprising lengths of RG59 coaxial cable 40 extending around the hotel and passive splitters 42, with active distribution amplifiers 44 being included as required to ensure that there is a sufficient signal level for each of the televisions 14. The distribution amplifiers 44 are preferably of the two-way type, so that the location where the television signals are put onto the distribution network 38 can be changed if desired without requiring substantial reconfiguration of the network 38. As shown schematically in Figure 3, each television 14 includes a tuner 48 connected to the aerial input 46, and the tuner 48 can be adjusted by the user to select the channel frequency of the channel that the user requires to be shown on the television 14.

There are a number of problems or disadvantages with a conventional distribution system as described above with reference to Figures 1 to 3. First, all of the channels are available to all of the televisions 14, and so special steps need to be taken if

it is desired to prevent a particular programme, such as a pay-per-view programme, from being viewed on a particular television 14. Second, there is a limit to the number of frequency-multiplexed channels that can be distributed by the network 38, because each television or video programme occupies a bandwidth of 6 MHz, and RG59 coaxial cable  
5 which is typically used in such an installation has a typical bandwidth of 460 MHz, so that the cable cannot satisfactorily carry more than seventy-six frequency-multiplexed channels. Third, the television/video signals are distributed as analogue signals, possibly over many tens of metres, and, in many instances, provide unsatisfactory picture quality.

In order to deal with these problems and disadvantages, the embodiment of the  
10 invention that will now be described with reference to Figure 4 uses a switched point-to-point digital distribution network 50 employing an internet protocol (IP) and in particular the user datagram protocol (UDP/IP). In the equipment room 16, the download 20 from the terrestrial television aerial 18 feeds a receiver and MPEG encoder 52 which provides digital MPEG video streams 54 for the received terrestrial television  
15 programmes to a server 56 (although one server 56 has been shown in the drawing, several such servers may be employed). Also, the download 24 from the satellite dish 22 feeds a decoder/descrambler 58 which provides digital MPEG video streams 60 for the received satellite television programmes to the server 56. Furthermore, the video replay equipment 62 has a digital output and provides digital MPEG video streams 64 for the  
20 video programmes to the server 56. The server 56 selects which of the video streams is to be transmitted to which room 12, and places the selected video streams on the digital network 50 using UDP/IP, or TCP/IP, each addressed to the selected room 12. In each room 12, the television 14 is connected to the network 50 by a local control unit (LCU) 66 that receives the video stream addressed to that room 12, decodes it, and supplies the  
25 resulting analogue video and audio signals to the television 14. Each LCU 66 is also operable to send requests over the network 38 to the server 56, for example to change the television/video channel supplied to that LCU 66.

The network 50 is designed to support a bandwidth of up to 10 Mbps for communication between the server 56 and each LCU 66. The components required to  
30 deliver this bandwidth will vary because of the different topology of each hotel - for example, the layout of floors, risers, and the location of the equipment room 16 in which

the server(s) 56 is/are situated.

The required bandwidth of 10 Mbps per LCU 66 can be delivered using a switched network built on one or more high speed (100 Mbps) switches 68 each having up to twenty three ports, for instance eleven ports, that are in turn linked to the server(s) 56 (and to each other) via a Gigabit switch or high speed backbone network linking switches 70. Each LCU 66 is connected to the network via such a 100 Mbps switch 68 and a Category 5 (ANSI/EIA/TIA-568-1991) unshielded twisted pair (UTP) cabling system 72 operating at up to 10 Mbps. Each switch 68 is connected to the backbone 74 using such a Gigabit switch 70 and a Category 5 UTP cabling system 76 operating at up to 100 Mbps. The server(s) 56 is/are connected directly to the Gigabit switch 70.

This architecture can be simplified for smaller installations that do not have high bandwidth requirements, by using 10/100 Mbps switches with fewer ports, and by using a lower speed cabling system for the backbone network.

The embodiment described above using Category 5 UTP cabling is efficient, scalable, manageable and cost-effective. It also uses many established components and widely available skills. From the network management perspective, this option is the most controllable and the easiest architecture on which to build other applications. However, the installation of the cabling 72,76 and switches 68 is disruptive and so installation into an existing hotel will make hotel rooms unavailable for a substantial period of time, which may be unacceptable to the hotel's owners. For this reason, this option may only be suitable for new hotels and the refurbishment of existing hotels.

To deal with this problem, the required bandwidth of 10 Mbps per LCU 10 can also be delivered using the RG59 baseband coaxial cable infrastructure 38 as shown in Figure 1 within an existing hotel 10. While this type of coaxial cable is of inferior quality to the coaxial cable used by providers of cable television to the residential market, the cable can be used for the transmission of data in a controlled environment - such as a hotel.

Low grade coaxial cable is traditionally used to supply analogue video to hotel rooms. Each television signal occupies a 6MHz bandwidth. The coaxial cable has a typical bandwidth of 460MHz, which allows up to 76 television channels to be

frequency multiplexed together and carried by the one cable network.

The losses over a 75  $\Omega$  RG59 television coaxial cable are typically 0.13 dB/m at 100 MHz, 0.19 dB/m at 200 MHz and 0.46 dB/m at 100 GHz. Such coaxial cable can be used without modification to carry digitally encoded MPEG video. Using digital  
5 encoding, each analogue channel is transformed to a "data pipe" with over 30Mbps of capacity. This pipe is used to carry a multiplex of video channels. The number of video channels that can be carried depends on the picture quality required. For received PAL TV picture quality, typically six video channels can be carried in each pipe.

The lowest frequency channel is used as a "back channel" to feed low data rate  
10 information from individual rooms back to the server 56. The back channel is operating at a much lower data rate and can withstand much worse signal-to-noise ratios than the wide-band analogue television signals. Therefore, the system can cope with the additional losses introduced by the return path on top of the losses from any distribution amplifiers used.

15 Digital video over coax generally uses a 64QAM modulation scheme, where groups of 6 bits are mapped to a carrier state. Each carrier state has a unique amplitude / carrier phase position as illustrated in Figure 8.

In order to decode 64QAM with an acceptable worst case error rate, before error correction, of 1 error in  $10^4$  bits, a signal-to-noise ratio per bit of greater than 18dB is  
20 needed. At a smaller signal-to-noise ratio each dot in the constellation will become blurred and it will not be possible to differentiate one dot from another. A 1.5dB difference in signal-to-noise level will make an order of magnitude difference in the error rate.

Higher order QAM schemes can be used to increase the data capacity of each  
25 channel. The increased capacity is gained at the price of needing a higher signal-to-noise ratio to properly decode the signal. Conversely, lower order schemes are more rugged but have a lower capacity.

MPEG compressed video and audio is sensitive to errors. A final error ratio of near 1 in  $10^{10}$  is needed for good quality pictures. Forward error correction schemes are

used to correct errors in the raw data stream to achieve the required error rate. The signal-to-noise ratios needed to demodulate 64QAM to obtain good quality MPEG encoded video are slightly less than that needed to receive an analogue TV channel. A major difference though, is that if the signal-to-noise ratio of the 64QAM signal  
5 degrades below the minimum required the picture rapidly degrades and is easily lost. With analogue TV the signal degradation is much more graceful. The signal-to-noise ratio of the transmitted signal will be much higher than that required for successful demodulation and decoding of the MPEG video. However, the coax network will degrade the signal. It will attenuate the signal, and noise will be introduced into the  
10 system by:

- Amplifiers - all amplifiers are not perfect and introduce some noise. The signal-to-noise ratio will be degraded by the noise figure of the amplifier, typically 3 to 5dB
- Ingress into the cable system from other RF transmissions and other electrical  
15 noise.

Maximum signal levels will be determined by the maximum practical levels any amplifiers can amplify to whilst maintaining their linearity (if the amplifiers compress, the outer points in the constellation will not be in the correct position) and regulatory EMC limits.

20 The existing coaxial cable infrastructure has a wide bandwidth and could be used for digital multimedia applications. When considering their suitability for a multimedia system a number of factors should be considered:

- The single point to multiple point topology means that the capacity of the one coaxial cable is the capacity of the entire network.
- 25 • Distribution amplifiers limit the up-link performance of the network. The bandwidth of the up-link may be limited to less than that required for excessively demanding up-link tasks.
- To improve the up-link performance, new distribution amplifiers would be needed to give improved up-link performance. Upgrading the infrastructure may  
30 be difficult and costly. Depending on whether any records have been kept, and the accuracy of such records, a major problem may be locating the existing

distribution amplifiers. Alternatively, removing the capability for fast up-link access may allow the use of existing cable.

- It is likely that the coaxial cable typically used in hotels is lower grade than that used in residential cable television. Ingress of signals from local terrestrial television channels may cause problems by interfering with the digital multimedia signals.
- The coaxial cable is not DC coupled and so cannot carry the low frequency data found in many data communication standards.
- As the present analogue television and the new digital multimedia system would occupy the same bandwidth on the same cable it would be difficult to convert the existing cable network to a digital multimedia whilst still supporting analogue television. This would rule out an incremental introduction of a multimedia service in a hotel.
- Depending on where in the network the fault is located, faults in the cable distribution system could affect services to one or many, possibly all, rooms of the hotel.
- Faults may be difficult to locate.
- Possible coax-based approaches include:
  - Operate as current digital cable TV does, with all channels broadcast (say 76 frequency channels multiplexed 6 ways), i.e. 456 available channels. Certain channels could carry broadcast TV and radio for access by any guest, with others dedicated to room-specific services. In this case, any room could receive any channel, however, the system would need a means of informing each room where to find the service it requested. This approach has the advantage of requiring equipment similar to current digital cable TV (i.e. cable modems etc.), but the channel identification problem is significant. Other issues, noted earlier, are the difficulty of partial upgrading, the risk of poor signal quality in the hotel cable system environment, poor amplifier linearity, and the provision of suitable bandwidth in the back-channel.
  - Provide the same 456 channels, but dedicate each to a room. Each channel can carry any of the services a room might require, with the server selecting the source. This method gives a higher limit to the number of rooms that can be

served, and removes the need for frequency channel selection and demultiplexing at the LCU. Other potential problems are as for the first method above (i.e. partial upgrading, poor signal quality, back-channel, etc.).

- Dedicate the whole cable to a single “pipe”, with time multiplexing (i.e. like Ethernet). Conceptually this seems attractive, but the equipment required to realise this would be very high performance, very expensive, and does not exist currently.

Of these coax-based approaches, the second is preferred.

Across conventional hotel television infrastructures, each programme is broadcast in analogue format on a separate channel within the coaxial cable 40, as already described with reference to Figures 1 to 3. The programmes are broadcast simultaneously and, when the guest changes programme, the television 14 picks up the requested programme by changing the frequency to which the tuner 48 is tuned. In more complex arrangements to that shown in Figure 1, any signals that are returned to the equipment room 16 are tagged with the identity of the room initiating the signal and sent up-stream using the lowest frequency channel. The partitioning of channels within coaxial cable in this fashion has, in the past, been ideal for the efficient and cost-effective delivery of broadcast services to television sets in many situations – home via RF, home via cable, hotel room via cable. However, it is only recently, with a desire to make more services available, including interactive services, that the demand for substantially more bandwidth on the return path has arisen. Despite schemes for allocating certain channels for non-broadcast services, these schemes are insecure as well as being complex to implement, maintain and administer. The underlying problem with the current method of partitioning bandwidth by service is that the channel carrying the service is physically separate from the channel that carries the response. While this is not an issue with broadcast services, it is a fundamental drawback to the delivery of interactive services.

As illustrated schematically in Figures 5 to 7, the issue of the physical separation of delivery and response channels is addressed by repartitioning the channels within the available bandwidth of the cable 40. Instead of allocating one service per channel (e.g. channel 5 in Figures 2 and 3 is the TERR1 television programme), the embodiment of

Figures 5 to 7 allocates one room per channel (e.g. channel 5 in Figures 6 and 7 is the service for Room 5). This changes the distribution of services from a "broadcast" model to a "point-to-point" model – similar to the local area network model used in business.

The repartitioning of the channels on the coaxial cabling 40 is achieved by installing a cable modem termination system 80 between the server 56 and the coaxial cable network 38, and a cable modem 82 in each LCU 66. As shown in Figure 6, the cable modem termination system 80 can be considered to comprise a cable modem 84 for each channel, and the server 56 can be considered to be able to connect each cable modem 84 selectably to any of the incoming video streams. Each cable modem 84 then transmits that video stream on a preset channel on the coaxial cable 40. As shown in Figure 7, the cable modem 82 in each LCU 66 is preset to a particular channel, i.e. the channel for the room 12 in which the LCU 66 is situated. Each channel carried in the coaxial cable 40 can thus be dedicated to a single LCU 66. The server 56 will only transmit the service requested by the LCU 66. This is a simple architecture to install, as few cabling changes have to be made between the server 56 and room 12, and no cabling changes need to be made in the room 12. However, depending on the number of rooms served by each spur of the coaxial cable network 38, it may be necessary to modify the configuration of the coaxial cables at each riser to ensure that each spur has enough channels to support the number of rooms it is intended to serve.

- It should be noted, in the system described with reference to Figures 5 to 7, that:
- two-way amplifiers 44 are provided at some of the nodes of the cabling system 38 to amplify/maintain the signal level of signals passing from the sub-branches (in Figure 5 such a sub-branch is represented by the line 40 leading from, for example, Guest Room 1 to the nearest amplifier 44 shown just to the right of Guest Room 2) of a branch (in Figure 5 such a branch is represented by the line 40 leading from, for example, the amplifier 44 shown just to the right of Guest Room 2 to the amplifier 44 shown just above equipment room 16) to that branch in addition to the signal level of signals travelling from the branch to the sub-branches;
  - a signal can be transmitted on one channel from one of the LCUs 66 to the server 56 generally at the same time as a signal is transmitted on another channel from

the server 56 to another of the LCUs 66; and

- the same channel is used for transmission from the server 56 to a particular LCU 66 as is used for transmission from that LCU 66 to the server 56.

Although it is known to use two-way amplifiers 44 in coaxial distribution  
5 systems as described with reference to Figure 1, they are employed to facilitate relocation of the location 16 where signals are put onto the system, rather than to enable the latter two features listed above, i.e. generally simultaneous transmission in both directions, and transmission between the server 56 and an LCU 66 in both directions on the same channel.

10 A number of digital television standards have been adopted by residential cable television suppliers. These standards typically allow for one or more of the 6MHz down-link channels to carry IP traffic at 27Mbps. Up-links operate at typically between 500Kbps and 10Mbps. A number of open and proprietary standards exist. Open standards include:

- 15
- DOCSIS (Data Over Cable System Interface Specification) is the standard for cable modem products in North America
  - DVB EuroModem is a standard designed to address European requirements.

In order to deal with the problem of disruption if installing a new network into an existing hotel, the required bandwidth of 10 Mbps per LCU can also be delivered using  
20 the telephone cable infrastructure within the hotel 10.

As shown in Figure 9, the hotel 10 might typically have a telephone socket 86 and telephone 88 in each room 12, and a private automatic branch exchange (PABX) 90 in the equipment room 16. Each telephone socket 86 is connected to the PABX 90 by a separate Category 2, or British Telecom CW1308, cable 92 having two twisted pairs, so  
25 as to provide a point-to-point network. The PABX is connected to the public switched telephone network (PSTN) with the required number of lines 94.

While this type of cable (Category 2) is of inferior quality to the standard network cable (Category 5) used in business offices, the cable can be used for the transmission of data in a controlled environment - such as the hotel 10, as shown in  
30 Figure 10. The equipment room 16 is provided with a server 56, satellite decoder 58,

MPEG encoder 52 for terrestrial television, digital video replay equipment 62 and Gigabit switch 70, similar to those described above with reference to Figures 4 and 5. Also, the Gigabit switch 70 is connected to a multiple splitter 98 inserted in the paths of the Category 2 cables 92 to the PABX 90, so that the cables 92 extending throughout the hotel 10 can carry the lower-frequency signals to and from the PABX 90 and the higher-frequency signals to and from the server 56. In each room 12, the standard telephone socket 86 is replaced by a wall box 100, as shown in greater detail in Figure 11, which includes a splitter 102 connecting the cable 92 both to the telephone 88 and to an LCU 66. The LCU 66 includes a network interface 104 and MPEG decoder 106, which decodes the digital video signal and supplies corresponding analogue video and audio signals to the television 14.

Traditional analogue telephone operates in the frequency band 300 to 3.3KHz. The twisted pair cable 92 does not have as wide a bandwidth as coaxial cable but the bandwidth is significantly wider for digital signals than the band used for analogue telephony. The actual bandwidth of data the cable can support depends on the distance it needs to be transmitted and the degree of interference or cross talk it is subjected to. For the typical cable distances in a hotel of say 100m, a data rate of up to 25 Mbps may be achieved in one direction. This is adequate for carrying an MPEG-2 encoded television channel.

As twisted pair cables tend to be run in bundles, cross talk between twisted pairs, rather than attenuation of the signal, tends to be the limiting factor affecting operating distances. Cross talk can be divided into two different categories, NEXT (Near End Cross Talk) and FEXT (Far End Cross Talk).

The difference between NEXT and FEXT and the consequences of the two effects can be understood by considering two twisted pairs bundled together going into a PABX:

- NEXT - If the PABX is transmitting a high level signal down one twisted pair whilst trying to receive a low-level signal from another twisted pair, cross-talk from the high level signal can easily swamp the low level signal
- FEXT - If the PABX is transmitting two high level signals down two twisted pairs cross-talk between the two pairs will still occur but will be at a low level.

NEXT tends to cause more problems than FEXT.

As the system of Figures 10 and 11 demands a high bandwidth down-link with a narrower bandwidth up-link, the effects of NEXT can be minimised. If all data is travelling in the down-link direction, from the server 56 to an individual hotel room 12, NEXT is not a problem. By allocating more bandwidth than is strictly needed for the data returning to the equipment room 16 the effects of NEXT can be minimised for up-link data.

Factors to consider for using the existing hotel telephone network for a multimedia system include:

- 10     • The overall capacity of the system is not limited by the capacity of any individual twisted pair cable
- The capacity to any individual room is limited by the capacity of the individual twisted pair. However this capacity is adequate for MPEG-2 video and other multimedia applications
- 15     • As long as the digital system used does not put any energy into the telephone channel bandwidth, the hotel multimedia system can co-exist with the existing telephone network
- A fault on an individual twisted pair cable will only affect the room the cable is linked to
- 20     • The upgrade from analogue television to a digital multimedia service can be done on an incremental room by room basis

Two standards utilising standard twisted pair telephone wires are possibly applicable to the embodiment of Figures 10 and 11. These are ADSL and Home PNA.

ADSL (Asymmetric Digital Subscriber Line) was originally proposed for video-on-demand applications over the 'local loop' between the telephone exchange and home. More recently, it has been used for high speed internet access over the same local loop. Both applications need higher down-link data rates than up-link data rates and so are suitable for an 'asymmetric' standard i.e. a higher down-link bandwidth relative to up-link bandwidth. This also minimises the problems of NEXT described above. ADSL typically has a range of downstream speeds depending on the distance. This includes

8.448 Mbps at distances of up to 2750 metres. Up-stream data rates range from 16 Kbps to 640 Kbps depending on application and individual product implementations. The standard is designed to operate at the same time as standard analogue telephone equipment. It does this by operating in the frequency range of 25KHz to 1MHz, leaving  
5 the lower frequency portion clear for standard telephone. As equipment using the standard is being deployed by a large number of telecommunications operators, both head end equipment suitable for many subscribers and consumer modem/set top boxes are available. As ADSL is designed for point to point links only, the splitters 98,102 will probably be needed, placed at both the head end and at the entrance to the hotel room.  
10 Their function is to ensure that additional lines going to the hotel PABX 90 or room telephone 88 do not form part of the ADSL network. Noise induced onto telephone lines tends to have a "bursty" nature. This badly affects real time services such as video by wiping out a block of data which error correction schemes find impossible to correct. In a real time system, there is no chance to retransmit the data as there is in data  
15 communication systems. To overcome this problem, ADSL interleaves blocks of data so that the errors caused by the noise burst become distributed "white" noise which causes occasional bit errors. These errors may then be rectified by standard error correction schemes, or may not need correction at all, as they are spread across the picture and so are not noticeable to the viewer. There is little doubt that ADSL is suitable for  
20 multimedia applications in hotels, but it may be considered over-specified for the task and so may be more expensive than necessary.

Home PNA is an alliance of over one hundred manufacturers who have devised a computer networking standard using the telephone cable network found in domestic homes. The alliance includes many large manufacturers such as IBM, 3COM and Intel.  
25 To access the standard, companies have to become an adopter member of the alliance. Two versions of the standard exist. The first is designed to operate at 1Mbps, which is clearly too slow for video, but may be suitable for other parts of the hotel system. The second operates at 10Mbps, which is more suitable. The technology is designed to operate concurrently with telephone and xDSL. It does this by operating at higher  
30 frequencies than either of these two technologies. As the standard is designed for applications in homes, a wide range of equipment is available for domestic applications at low cost. This equipment would be suitable for use in hotel rooms.

It is clear that the coaxial solution of Figures 5 to 8 meets the down-link requirements but may not easily meet those of the up-link. It may be possible to use a hybrid solution that uses the coaxial cable as a down-link and the telephone system as the up-link. A possible solution may be to use the coaxial cable for frequency multiplexed, MPEG encoded television channels with the rest of the services carried on, for instance, a 1Mbit HomePNA network. Any hybrid solution is not likely to be as neat a solution as a single network solution, as it is likely to need two connections to the LCU 66 located in the hotel room 12. Two chipsets will be needed in the LCU 66, one to decode the MPEG video, the other for the remaining applications.

Of the methods for providing a network discussed above, clearly Category 5 cabling (Figure 4) is the simplest and most realisable. However, in order to supply to hotels yet to be re-furbished, the alternatives are provided of a coaxial cable based system, preferably with each channel dedicated to a room (Figures 5 to 8), and a telephone line based approach (Figures 10 and 11).

The heart of the system within the hotel room is the LCU 66, which acts as an interface between the guest and the server 56. Some of the functions of the LCU 66 are similar to set top boxes (STB) used to access broadcast digital television signals, and the LCU 66 can therefore utilise many of the components designed for these devices. The LCU 66 may be provided in a box separate from the television 14, or it may be physically located inside the television set 14. A major difference between the LCU 66 and a conventional STB is that the down-link data will be specific to that box and not broadcast. This means that there is no requirement for user-adjustable "tuner" circuitry found in conventional STBs, as the LCU 66 will in effect be "tuned" to one fixed channel, and the server 56 will ensure that the correct data is transmitted on that channel.

Figure 11 shows a block diagram of the proposed architecture for the LCU 66, the heart of which is an STB chip-set 118, which is shown in Figure 12. Instead of the "tuner" circuit, the LCU 66 has a network interface circuit 104 that receives data from the communications network (be it based on Category 5, coaxial, or Category 2 cabling) and passes it on to the television 14 for display. The guest controls the LCU 66 via an infra-red remote control 110, which may also include a keyboard so that the guest can enter alphanumeric and other characters. Video and audio signals 112 are passed to the

television 14 using standard signal formats such as RGB, CVBS or S/VHS, along with stereo audio channels.

The LCU 66 is able to control the functions of the television 14, via a proprietary control interface circuit 114, so that the guest can use a single remote control unit 110 to  
5 adjust television parameters such as volume, brightness, colour etc. Additionally, this interface circuit 114 allows the server 56 to control the television 14 so as to display the time and turn on the television 14 for alarm calls, welcome messages, etc. One requirement for the LCU 66 is that it should not be proprietary to any one make of television, so a mixture of a generic card 116 (carrying the STB chip set 118, network  
10 interface circuit 104, etc.), software configurability and one or more daughter cards, such as the television control interface circuit 114, are used to overcome the problem of different proprietary interfaces to different makes of television sets.

Three different types of data are sent from the server 56 to the LCU 66, all of which enter the LCU 66 via the network interface circuit 104:

- 15 • Control commands
- Video and audio streams
- Other user data.

A central processor (CPU) 120 interprets commands directly, while other user data may, for example, be converted to graphical images by application software  
20 running on the CPU 120. The graphical image is built up in a frame buffer that is part of the video encoder circuitry 122. The digital video stream from the server 56, which is compressed using MPEG-2 compression techniques, is passed to an MPEG decoder 124 where it is converted to graphical images, which are also passed into the frame buffer in the video encoder 122. Unlike conventional STBs, the LCU 66 will not need to handle  
25 MPEG transport de-multiplexing and de-scrambling, since these functions are handled by the server 56. The LCU 66 will receive a single unscrambled MPEG stream. The video encoder 122 takes the bitmap image in the frame buffer and produces the analogue signals 112 that are passed to the television set. These signals 112 can be in various different standard formats such as RGB, CVBS and S/VHS. If possible, RGB is the  
30 preferred option as it gives the best picture quality (using the television set 14 as a monitor). However, not all television sets 14 can support this format of input, so an

alternate such as CVBS (also known as “composite video”) is also supported.

One of the requirements for the video encoder circuit 122 is to be able to generate pictures in either PAL or NTSC formats, as there is no single world standard (generally Europe uses PAL and the U.S. uses NTSC). The French SECAM standard  
5 probably need not be supported, as a PAL system could be used instead.

One final task which the video encoder 122 may perform is to add Macrovision copy protection encoding. This alters the synchronisation signals in such a way as to make recordings unviewable without altering the picture when viewed on the television  
14. Use of this technology is often required when films are made available for  
10 presentation on a pay-per-view basis prior to their general release on video. Because of the way in which Macrovision works, the RGB output has to be disabled, so when enabled, the CVBS or S/VHS outputs will need to be used.

Audio signals are either extracted from the MPEG stream or created by the processor 120 (i.e. from a “.wav” file or other streaming audio source) and converted to  
15 stereo analogue signals using a digital to analogue coder/decoder. Some chipsets now offer Dolby Digital audio decoding as well as standard MPEG decoding.

In the case of a requirement for the LCU 66 to run the application software with complex graphics, the CPU 120 is preferably based on a powerful 32-bit core. To enable the MPEG stream to be decoded, a minimum of 2Mbytes of SDRAM are required, but  
20 most chip-sets 108 would require another 2Mbyte for processor applications. Use of a unified memory architecture removes the need for VRAM, by placing the frame buffer in the SDRAM. Additional hardware is also often included to render the images so that they do not “flicker” when displayed on the television 14.

All the application code, and the operating system code, is stored in Flash  
25 memory 126, so that the code can be upgraded. The memory controller to drive the SDRAM and Flash memory 126 is included on-chip, along with various peripheral controllers to interface to the EEPROM 128 and other devices. The IBM STB03xxx chip-set may be used for the LCU 66.

In view of the desire to install the system in an existing hotel 10 having existing

television sets 14, it is desirable that the LCU 66 be able to connect to a diverse range of television sets without the need for manufacturing too many permutations of the LCU 66. There are two ways of addressing this requirement:

- the LCU 66 can be manufactured as a separate unit that can be securely mounted in the room 12; for example, attached to the base of the television 14 or securely fixed to the wall
- the LCU can be manufactured as a card that can be inserted into a slot on the television chassis, providing that the television 14 has a suitable chassis.

When the generic card 116 of the LCU 66 is provided in a stand-alone box 130, as shown in Figure 13, there are the advantages that:

- all of the common components can be built into the stand-alone box and components, such as the control adapter circuit 114, specific to the model of television set 14 can be built onto a daughter card 132 that slots into a slot 136 on the chassis 134 in the television 14;
- servicing of the television 14 can be managed independently from servicing of the stand-alone box 130;
- television sets 14 can be upgraded without the need to replace the stand-alone box 130; and
- the stand-alone box 130 can be moved to smaller hotels that have less demanding requirements for functionality.

However, the casing for the stand-alone box 130 will in itself be a discrete cost, and different casings will also have to be manufactured for each model of television 14 if the casing is to be attached to the base of the television 14. Servicing will also be more difficult, as the system will comprise two physically separate components rather than a single integrated unit. There are also issues surrounding the security of the stand-alone box 130 and the potential maintenance issues raised when guests “tamper” with the stand-alone boxes 130.

Apart from the obvious aesthetic advantage, mounting the LCU 66 inside the television 14, as shown in Figures 14 and 15A and 15B, will simplify the power supply design, using the television’s own power supply unit to generate a raw DC supply, and

electro-magnetic capability (EMC), using the shielding already inside the television.

Many of the issues raised by providing the LCU as a stand-alone box can be negated by incorporating the LCU 66 within the television set 14. There is also a significant cost saving from not having to manufacture the casings for the stand-alone boxes. However, to incorporate the LCU 66 within the television set 14 as shown in Figure 14, the chassis 134 would need to provide a slot 138 for the installation of the generic card 116 providing the core functionality of the LCU 66 interfacing with the slot 136 in which the daughter card 132 is installed that transposes the input and output streams from the LCU to a format understood by the television set. Only one type of generic card 116 would be required for all televisions (or three types for the three types of network cabling used), whereas the daughter card 132 would be specific to each make and model of television set 14. Alternatively, as shown in Figure 15A, the generic card 116 may be installed in a slot 140 provided on the television-specific card 132. This latter arrangement may be modified as shown in Figure 15B in which the STB chip-set 118 is provided on a first television-generic card 116 installed in a first slot 140 on the television-specific card 132, and the network interface circuit 104 is provided on a second television-generic card 117 installed in a second slot 141 on the television-specific card 132. The card 132 is then specific to the make and model of television set 14, the second television-generic card 117 is generic for different makes and models of television set 14 but is specific to the type of network cabling that is used (e.g. Category 5, telephone or coaxial), and the first television-generic card 116 is completely generic.

While new television sets are built with chassis that support interface cards, older sets may not, so the manufacture of stand-alone boxes 130 may be unavoidable if all situations are to be covered.

Off-the-shelf software products may be used in the LCU 66, including a real-time operating system (RTOS), such as RTOS Red Hat Linux and system software bundled with Red Hat Linux. The chosen RTOS should provide support for the chosen chip-set and the ability to control streaming video. Any chosen RTOS should also support a TCP/IP stack and drivers for the network interface circuit 104. The RTOS controlling the LCU 66 may also provide several auxiliary services, such as:

- Proxy IP Server; to map the IP address of an external computer connected to the

LCU 66 to the IP address of the LCU 66

- DHCP Client; for dynamic allocation of an IP address to the LCU 66
- SNMP Client; to send SNMP traps containing diagnostic information to the server 56
- 5     • NFS Client; to allow the LCU 66 to connect to a network file system through the server 56
- Digital to Analogue Converter; a service to manage the decompression of an MPEG2 stream from the server 56 and its transposition to an analogue stream that will be routed to the television 14.

10       Code to control the low-level functionality of the chip sets 118 is best obtained directly from the chip-set manufacturer's reference design. If this can be done it means that the only code that needs to be newly written would be the top-level user interface.

Referring now to Figures 16 and 17, a development of the equipment provided in each room 12 will now be described. Figure 16 shows an LCU 66 similar to that shown  
15   in Figure 12 for use in a Category 5 network like that shown in Figure 4.

In addition to the features described with reference to Figure 12, the LCU 66 includes non volatile memory 154 which stores a unique address for the LCU 66.

The Category 5 cable 72 leading to each room 12 is connected to a wall box 142 having a conventional RJ45 socket 144 to which the network interface circuit 104 of the  
20   LCU 66 is connected by a Category 5 patch cable having an RJ45 plug 148. An address processor circuit 150 is contained in the wall box 142 and includes non-volatile memory 152 storing a unique address for the wall box 142. The address processor 150 is operable to respond to a request from the LCU 66 by returning the stored wall box address to the LCU 66.

25       When the system is installed, the system server 56 is set up to store a list of the addresses of all of the wall boxes 142 in the hotel, and when each LCU 66 is installed in a room 12, the address of the LCU 66 is stored in the list on the server 56 against the wall box address for that room 12.

The CPU 120 in each LCU is programmed to perform the boot processes

illustrated in Figure 17 when it is powered up. In step 156, the CPU 120 performs some preliminary boot processes. Then, in step 158, the CPU 120 causes a request to be sent to the wall box 142 for the box address stored in the wall box 142, and the address processor 150 in the wall box 142 responds with the address stored in the memory 152.

5 The CPU 120 receives the response in step 160. Then, in step 162, the CPU 120 reads the LCU address stored in the memory 154 and causes a request, including the LCU address, to be sent to the server 56 for the box address stored on the server 56 corresponding to that LCU address, and the server 56 responds with the stored address. The CPU 120 receives the response in step 164. Then, in step 166, CPU 120 determines

10 whether the address received from the address processor 150 in step 160 matches the address received from the server 56 in step 164. If so, then in step 168, the CPU 120 completes the boot processes so that the LCU 66 is fully operational. However, if the addresses do not match, the CPU 120 may perform any of several actions. For example, it may simply power-off, or it may continue booting to a safe mode, as shown in step

15 170, for example so that it is not operational except to cause a warning or advice message to be displayed on the television, and/or it may cause a message to be sent to the server 56, as shown in step 172, for example including the addresses of the LCU 66 and wall box 142, which may in turn trigger a message to the hotel security guard.

It will therefore be appreciated that an LCU 66 will not fully boot unless it is

20 connected to the wall box 142 designated for that LCU 66 in the list stored on the server 56.

Although the address processor 150 has been described above as being incorporated in a wall box 142 in the particular room 12, it should be noted that other locations are possible, such as at the room ports of the switches 68 in Figure 4, at the

25 room outputs of the splitters 42 and amplifiers 44 in Figure 5, at the splitter 98 in Figure 10, or in-line in a permanent cable in the room 12.

It should be noted that a similar development may be made to the systems employing coaxial cable or telephone cable.

The server 56 will now be described in more detail, also with reference to Figure

30 18. The server 56 controls the collation and distribution of stream-based media services

within a hotel environment. The server 56 provides a number of classes of media content, such as terrestrial television channels, terrestrial radio channels, digital satellite television channels, and pre-digitised media assets (movies).

5 The server 56 processes these input streams in a variety of formats (analogue, digital, compressed, encrypted, etc.) and outputs digital streams in MPEG-2 format to the switch 70 that supports Internet Group Management Protocol (IGMP). A channel controller uses IGMP to allow LCUs 66 to subscribe to any of the shared stream-based media services. The UDP/IP transport protocol is used for transmitting MPEG-2 streams to the LCU 66.

10 The server 56 comprises media capture, compression, and streaming functions and includes a media manager 174 that handles media-related events. The media manager 174 collects channel and schedule information from a configuration manager 176 and then passes messages to a specific channel manager 178. These messages detail actions that need to be taken; for example, loading an asset file, or streaming an asset on  
15 a particular card/channel. The configuration manager 176 holds a central repository of system-wide information. This data is used to control many aspects of a particular installation. A subset of the configuration manager database holds information specific to the server 56. This identifies the various servers, the cards that are registered, the channels that have been assigned, the loaded media assets and the overall schedule.

20 The server architecture supports both live and stored audio and video delivery. Live feeds are converted using specialised digitiser boards, compressed using hardware codecs, split into packets, and encapsulated inside an application transport protocol before final delivery on the network. Stored media files may be held in a compressed format in the media repository. These are loaded locally on the server 56 and are  
25 delivered in a similar manner on a scheduled basis.

The system supports the delivery of terrestrial television and radio, satellite television and pre-digitised media streams. Analogue streams, such as local television and radio channels, are captured and compressed prior to distribution. The delivery of analogue or digital television and radio requires efficient data capture and compression.  
30 This capability is available through hardware video and audio capture cards 180-184.

These cards allow the capture of a variety of analogue and digital streams from television and radio, and the generation of digital streams in MPEG-2 format for video, or MP3 format for audio. However, these cards operate on one specific input channel, and so a single card is provided per channel. The MPEG-2 or MP3 stream that is  
5 generated by each card is routed directly to an address and port on the network.

Referring also to Figures 19 to 23, the server may include the following components: television and radio cards 180,182,184,188 that receive analogue RF and satellite signals and convert them to digital signals in MPEG-2 format; television and radio cards 190 that receive digital signals in MPEG-2 format; playout cards 186 that  
10 multicast an MPEG-2 or MP3 file over the hotel network; and the software for the server 56, e.g. the channel manager 178, streaming components, etc. The server 56 may, for example, be presented as an 8 unit rack for mounting in a "19 inch" cabinet. Inside the cabinet there are a motherboard (e.g. Intel 700MHz processor, 256MB RAM, and 18GB disk), a PCI bus 191 with 24 slots for the media cards, a 100 Mbps network card 238,  
15 power supply and fan. The server uses a DHCP client to request IP addresses for each card installed, and an SNMP client that will report any change in the status of the cards to an SNMP server in the channel controller. Each media card 180-190 installed in the server 56 is connected to the IGMP switch 70 by a Category 5 fly lead 193 from the RJ45 port 192 on the card to a port on the switch 70. If more than one server 56 is  
20 provided, each server 56 is connected to a hub, so they can communicate with other devices on the network. As already described, the switch 70 is connected to the network 38,50 via its up-link port. The switch supports IGMP and runs at 100 Mbps. The number of ports on the switch 70 and the number of switches will depend on each installation.

The card 182 used for an analogue terrestrial television channel is shown in  
25 Figure 19. One such card 182 is installed in the server 56 per analogue local television channel that the hotel wants to receive. The server 56 uses a DHCP client to request the IP addresses for each card 182 installed. Each card supports an SNMP client that reports any change in the status of the card 182 to the SNMP server. The input port 194 of the first card is connected to the television aerial 18. Additional cards can be added as  
30 required to the server 56 and, in this type of environment, a distribution amplifier is used to ensure that the source signal strength is consistent between all cards 82. A hardware

failure on one card will not affect the functioning of other cards. The listening frequency of the demodulator 196 on each analogue television card 182 is under software control. The table below tracks the path of the stream sequentially through the analogue television card 182, starting at the television aerial 18 and terminating at the RJ45 output port 192 on the card.

Analogue Terrestrial Television Card 182			
Component	Path of Signal	Format	Notes
TV aerial system	TV aerial 18	Analogue, Modulated, Uncompressed	
	Coaxial cable 20	Analogue, Modulated, Uncompressed	
Television Card	Coaxial input port 194	Analogue, Modulated, Uncompressed	
	Demodulator 196	Analogue, Uncompressed	The listening frequency is under software control
	Analogue to digital converter 198	Digital, Uncompressed	
	MPEG-2 Compressor 200	Digital, MPEG-2	
	RJ45 output port 192	Digital, MPEG-2	An IP address is assigned to the port by a DHCP client on the server 56

Turning now to the processing that is performed to convert the analogue radio frequency signals on which satellite channels are delivered to the hotel via satellite dish 22 into digital streams in MPEG-2 format, ideally the analogue satellite card 188 (Figure 20) should receive signals directly from the satellite dish, de-scramble these and then select the appropriate channel, and convert the output to an MPEG stream. However, most of the satellite distributors use proprietary software and hardware to ensure that programmes are only received by registered subscribers. As a result, a set-top box 202 is required to receive, decrypt and transmit the required channel as a RF signal. The actual satellite card then becomes identical to the terrestrial TV card 182 (Figure 19). With this approach a set-top box 202 is required for each satellite channel that is to be distributed within the hotel.

One card 180,188 will be installed in the server 56 per satellite channel that the

hotel wants to receive. The server 56 uses a DHCP client to request IP addresses for each card 180,188 installed. Each card 180,188 supports an SNMP client that reports any change in the status of the card to the SNMP server. The input port 194,204 of the first card is connected to the coaxial cable from the satellite dish. Additional cards can be added as required to the server 56. Where multiple cards are deployed a distribution amplifier is used to ensure that a consistent source signal strength is available to all cards. A hardware failure on one card will not affect the functioning of other cards. The listening frequency of the demodulator on each analogue satellite receiver card 180,188 will be under software control. The descrambling algorithms will also be under software control, if possible. The table below tracks the path of the stream sequentially through the analogue satellite receiver card 188, starting at the satellite dish 22 and terminating at the RJ45 output port 192 on the card 188.

Analogue Satellite Television Card 188			
Component	Path of Signal	Format	Notes
Satellite Receiver System	Satellite dish 22	Analogue, Scrambled, Multiplexed, Uncompressed	
	Coaxial cable 24	Analogue, Scrambled, Multiplexed, Uncompressed	
Satellite Receiver Card	Coaxial input port 204	Analogue, Scrambled, Multiplexed, Uncompressed	
	Descrambler 208	Analogue, Multiplexed, Uncompressed	
	Demultiplexer 210	Analogue, Uncompressed	The selected channel is under software control
	Analogue to digital converter 212	Digital, Uncompressed	
	MPEG-2 Compressor 214	Digital, MPEG-2	
	RJ45 output port 192	Digital, MPEG-2	An IP address is assigned to the port by a DHCP client on the server 56

Turning now to the processing that is performed to convert analogue frequency signals on which local radio is delivered to the hotel via a roof-top aerial 216 into digital streams in MPEG-2 format, one card 184 (see also Figure 21) is installed in the server

56 per analogue radio channel that the hotel wants to receive. The server 56 uses a DHCP client to request IP addresses for each card 184 installed. Each card 184 supports an SNMP client that reports any change in the status of the card to the SNMP server. The input port 218 of the first card is connected to the radio aerial lead 220. Additional cards are chained together in serial using coaxial cable. The last card in the series has a terminator installed on the input port. The listening frequency of the demodulator 222 on each analogue radio card 184 is under software control. The table below tracks the path of the stream sequentially through the analogue radio card 184, starting at the radio aerial 216 and terminating at the RJ45 output port 192 on the card 184.

Analogue Radio Card 184			
Component	Path of Signal	Format	Notes
Radio aerial system	Radio aerial 216	Analogue, Modulated, Uncompressed	
	Coaxial cable 220	Analogue, Modulated, Uncompressed	
Radio Card	Coaxial input port 218	Analogue, Modulated, Uncompressed	
	Demodulator 222	Analogue, Uncompressed	The listening frequency is under software control
	Analogue to digital converter 224	Digital, Uncompressed	
	MP3 Compressor 226	Digital, MP3	
	RJ45 output port 192	Digital, MP3	An IP address is assigned to the port by a DHCP client on the server 56

10 In the case of the reception of digital satellite television, a card 190 (Figure 22) may be employed having a descrambler 230 and demultiplexer 232. The table below tracks the path of the stream sequentially through the digital satellite television card 190, starting at the satellite dish 22 and terminating at the RJ45 output port 192 on the card 190.

Digital Satellite Television Card 190			
Component	Path of Signal	Format	Notes
Satellite Receiver System	Satellite dish 22	Digital, Scrambled, Multiplexed, MPEG-2	
	Coaxial cable 24	Digital, Scrambled, Multiplexed, MPEG-2	
Satellite Receiver Card	Coaxial input port 228	Digital, Scrambled, Multiplexed, MPEG-2	
	Descrambler 230	Digital, Multiplexed, MPEG-2	
	Demultiplexer 232	Digital, MPEG-2	The selected channel is under software control
	RJ45 output port 192	Digital, MPEG-2	An IP address is assigned to the port by a DHCP client on the server 56

The play-out cards 186 that store MPEG-2 files on the server 56 and stream these files within the hotel will now be described, also with reference to Figure 23. The play-out cards 186 stream stored MPEG-2 files over the hotel network infrastructure. The play-out cards 186 have the same delivery capability as the other cards 180-184. Each of these cards shares the same on-board "packetisation" and delivery software. However, the play-out card 186 differs in two respects: it performs no MPEG-2 encoding and it supports the delivery of multiple channels.

The server 56 is configured with the following components: three or more 18 GB (min.) wide SCSI hard disk drives 234; a RAID 5 disk controller card 236; and a 100BaseT network card 238.

When the media manager 174 notifies the channel manager on the server 56 to start playing a particular media asset (film) it instructs the play-out card 186 to load and process a local copy of the file and stream this direct through its 100 BaseT network port 192. This will in turn connect to the IGMP switch 70, so that LCUs 66 associated with the appropriate IGMP group will receive the MPEG-2 stream. The local disk array 234 holds the required films as MPEG-2 format files. The server 56 uses a DHCP client to request IP addresses for each network component installed. Each card supports an SNMP client that reports any change in the status of the card to the SNMP server. The following parameters will be under software control: the full filename and path for the

media assets; the channels associated with each card; and the asset to be streamed on a particular channel. The table below tracks the path of the stream sequentially through the server when the asset is played.

Media Play-out			
Component	Path of Signal	Format	Notes
Media server	Disk drive 234	Digital, MPEG-2	The server is notified to stream a particular asset on a defined channel. The play-out card 186 is notified that a specific file is to be opened and streamed.
	RJ45 output port	Digital, MPEG-2	An IP address is assigned to the port by a DHCP client on the server 56.

5 In any or all of the aforementioned, certain features of the present invention have been implemented using computer software. However, it will of course be clear to the skilled man that any of these features may be implemented using hardware or a combination of hardware and software. Furthermore, it will be readily understood that the functions performed by the hardware, the computer software, and such like are  
10 performed on or using electrical and like signals.

Features which relate to the storage of information may be implemented by suitable memory locations or stores. Features which relate to the processing of information may be implemented by a suitable processor or control means, either in  
15 software or in hardware or in a combination of the two.

Analogous method steps to the apparatus features described herein are provided within the scope of the invention, and vice versa. In any or all of the aforementioned, different features and aspects described above, including method and apparatus features  
20 and aspects, may be combined in any appropriate fashion.

The Applicant asserts design right and/or copyright in the accompanying drawings.

25 It will be understood that the present invention(s) has been described above

purely by way of example, and modifications of detail can be made within the scope of the invention.

Each feature disclosed in the description, and (where appropriate) the claims and  
5 drawings may be provided independently or in any appropriate combination.

CLAIMS

1. A system for distributing television/video signals to different locations, the system comprising a server capable of providing digital television/video signals for a plurality of programmes, a plurality of receivers each at a respective one of said locations, and a network connecting the server to the receivers, each receiver being operable to select a required one of the programmes and to communicate the selection to the server, the server being responsive to such a selection to transmit the digital television/video signal for the selected programme over the network addressed to the receiver that selected that programme, and each receiver being responsive to the digital television/video signal that is addressed to that receiver so that point-to-point communication is established from the server to that receiver.
2. A system according to claim 1, wherein the different locations are different rooms in a hotel.
3. A system according to claim 1, wherein the different locations are different dwellings in a neighbourhood.
4. A system according to any of claims 1 to 3, wherein a substantial part of a cable run of the network from the server to at least one of the receivers is provided by data grade twisted-pair cable.
5. A system according to claim 4, wherein the twisted-pair cable substantially complies with or exceeds the specification of ANSI/EIA/TIA-568-1991, Category 3.
6. A system according to claim 4, wherein the twisted-pair cable substantially complies with or exceeds the specification of ANSI/EIA/TIA-568-1991, Category 5.
7. A system according to any of claims 1 to 6, wherein a substantial part of a cable

run of the network from the server to at least one of the receivers is provided by telephone-grade twisted-pair cable.

8. A system according to claim 7, wherein the twisted-pair cable falls below the specification of ANSI/EIA/TIA-568-1991, Category 3.
- 5 9. A system according to claim 7 or 8, wherein the twisted-pair cable does not substantially exceed British Telecommunications specification CW1308, or is of the type known as Category 2 twisted-pair.
10. A system according to any of claims 7 to 9, wherein the twisted-pair cable has a characteristic impedance at 16 MHz substantially higher than 115  $\Omega$ .
- 10 11. A system according to any of claims 7 to 10, wherein the twisted-pair cable has less than four twisted pairs.
12. A system according to any of claims 1 to 11, further including a telephone connected by a first splitter to the network adjacent the respective receiver, and a telephone exchange connected by a second splitter to the network remote from  
15 the respective receiver.
13. A system according to claim 12 as dependent on any of claims 7 to 11, wherein the telephone is connected by the first splitter to the telephone grade cable, and the telephone exchange is connected by the second splitter to the telephone grade cable.
- 20 14. A receiver for use in a system for distributing television/video signals to different locations, the system comprising a server capable of providing digital television/video signals for a plurality of programmes, the receiver comprising means for enabling connection to the server by means of a network, means for selecting a required one of the programmes, and means for communicating the

selection to the server, the receiver being responsive to a digital television/video signal that is transmitted by the server over the network and addressed to that receiver so that point-to-point communication is established from the server to that receiver.

- 5 15. A receiver according to claim 14, wherein the receiver is tuned to a given channel.
16. A receiver according to claim 14 or 15, further comprising means for converting the digital signals to analogue signals for supply to a picture/sound reproduction means.
- 10 17. A receiver according to claim 16, wherein the digital to analogue converting means includes means for decompressing the digital signals.
18. A receiver for use in a system for distributing television/video signals to different locations, the system comprising a server capable of providing digital television/video signals for a plurality of programmes, the receiver comprising a  
15 connection to the server via a network, a selector for selecting a required one of the programmes, and a transmitter for communicating the selection to the server, the receiver being responsive to a digital television/video signal that is transmitted by the server over the network and addressed to that receiver so that point-to-point communication is established from the server to that receiver.
- 20 19. A receiver substantially as described particularly with reference to, or as illustrated in Figures 11 and 12 of the drawings.
20. A method of installing a distribution system according to any of claims 7 to 12 for premises having an existing arrangement of telephone cable for a telephone system of the premises, the method including using at least part of the existing  
25 arrangement of telephone cable in the network of the distribution system.

21. A method of installing a system for distributing television/video signals for premises having an existing arrangement of telephone cable for a telephone system of the premises, substantially as described particularly with reference to, or as illustrated in Figures 9 to 11 of the drawings.
- 5 22. A system according to any of claims 1 to 12, wherein a substantial part of a cable run of the network from the server to a plurality of the receivers is provided by a conductor arranged to carry the digital television/video signals for those receivers, those signals being provided on respective channels each allocated to a respective one of the receivers, and each receiver being tuned to its respective  
10 channel.
23. A system according to claim 22, wherein the conductor is coaxial cable.
24. A system according to claim 23, wherein the coaxial cable is analogue television grade coaxial cable.
25. A system according to claim 23 or 24, wherein the coaxial cable has a  
15 characteristic impedance of 75  $\Omega$ .
- 26 A system according to any of claims 23 to 25, wherein the coaxial cable is substantially in accordance with specification RG59 or RG62.
27. A system according to any of claims 23 to 26, wherein each of the plurality of receivers is connected to the coaxial cable *via* a cable modem whose tuning is  
20 preset to the channel allocated to the respective receiver.
28. A system according to any of claims 23 to 27, wherein the server is connected to the coaxial cable *via* a cable modem that is controlled by the server to place the digital television/video signal for the programme selected for each receiver on the channel allocated to that receiver.

29. A method of installing a distribution system according to any of claims 12 to 28 for premises having an existing arrangement of coaxial cable for distributing analogue television signals in or to the premises, the method including using at least part of the existing arrangement of coaxial cable in the network of the distribution system.
30. A method of installing a system for distributing television/video signals in premises having an existing arrangement of coaxial cable for distributing analogue television signals in or to the premises, substantially as described particularly with reference to, or as illustrated in Figures 1 and 5 to 7 of the drawings.
31. A system for distributing television/video signals to different locations, substantially as described particularly with reference to, or as illustrated in Figure 4, Figures 5 to 7, or Figures 10 and 11 of the drawings.
32. A method of distributing television/video signals to different locations, the method comprising providing a server capable of providing digital television/video signals for a plurality of programmes, providing a plurality of receivers each at a respective one of said locations, providing a network connecting the server to the receivers, each receiver selecting a required one of the programmes and communicating the selection to the server, the server responding to such a selection and transmitting the digital television/video signal for the selected programme over the network addressed to the receiver that selected that programme, and each receiver responding to the digital television/video signal that is addressed to that receiver so that point-to-point communication is established from the server to that receiver.
33. A method according to claim 32, wherein the transmitting includes transmitting the digital television/video signal over telephone-grade twisted-pair cable.
34. A method according to claim 32 or 33, wherein the transmitting includes

transmitting the digital television/video signal over coaxial cable on a channel allocated according to the receiver to which the signal is being sent, and each receiver being tuned to its respective channel.

- 5 35. A networked system comprising a server and a plurality of devices at different locations connected to the server by a network, at least part of the network being provided by a conductor for carrying a plurality of signals between the server and the devices, the signals being multiplexed on the conductor each on a preset channel allocated according to the device so that each device has a respective preset one of the channels.
- 10 36. A system according to claim 35, wherein the signals are frequency-multiplexed on the conductor.
37. A system according to claim 35 or 36, wherein the signals are phase-multiplexed on the conductor.
- 15 38. A system according to any of claims 35 to 37, wherein the signals are digital signals.
39. A system according to any of claims 35 to 38, wherein the conductor is an electrical conductor and the signals are electrical signals.
40. A system according to claim 39, wherein the conductor is a coaxial cable.
- 20 41. A system according to claim 40, wherein the coaxial cable is analogue television grade coaxial cable.
42. A system according to claim 40 or 41, wherein the coaxial cable has a characteristic impedance of 75  $\Omega$ .

43. A system according to any of claims 40 to 42, wherein the coaxial cable is substantially in accordance with specification RG59 or RG62.
44. A system according to any of claims 35 to 38, wherein the signals are optical signals and the conductor is an optical conductor.
- 5 45. A system according to any of claims 35 to 44, wherein the network provides two-way communication between the server and each terminal, the same channel being used for communication from the server to a particular one of the devices as for communication from that device to the server.
- 10 46. A networked system substantially as described particularly with reference to, or as illustrated in Figures 5 to 7 of the drawings.
47. A method of operation of a networked system comprising a server and a plurality of devices at different locations connected to the server by a network, at least part of the network being provided by a conductor for carrying a plurality of signals between the server and the devices, the method including multiplexing  
15 the signals on the conductor each on a preset channel allocated according to the device so that each device has a respective preset one of the channels.
48. A method of operation of a networked system comprising a server and a plurality of devices at different locations connected to the server by a network, at least part of the network being provided by coaxial cable having at least one branch  
20 which is divided at a node into at least two sub-branches in a path direction extending away from the server, and a two-way amplifier being provided at the node to amplify/maintain the signal level of signals passing from the sub-branches to the branch in addition to the signal level of signals travelling from the branch to the sub-branches, the method comprising transmitting a signal from  
25 at least one of the devices to the server generally at the same time as transmitting a signal from the server to the devices.

49. A method according to claim 48, further comprising transmitting the signals from the server to the devices on different channels allocated according to the device, and transmitting signals from each device to the server on the same channel as is used for transmission from the server to that device.
- 5 50. A method of operation of a networked system comprising a server and a plurality of devices at different locations connected to the server by a network, at least part of the network being provided by coaxial cable having at least one branch which is divided at a node into at least two sub-branches in a path direction extending away from the server, and a two-way amplifier being provided at the  
10 node to amplify/maintain the signal level of signals passing from the sub-branches to the branch in addition to the signal level of signals travelling from the branch to the sub-branches, the method comprising transmitting the signals from the server to the devices on different channels allocated according to the device, and transmitting signals from each device to the server on the same  
15 channel as is used for transmission from the server to that device.
51. A method of operation of a networked system substantially as described particularly with reference to, or as illustrated in Figures 5 to 7 of the drawings.
52. A networked system comprising a server and a plurality of devices at different locations connected to the server by a network, at least part of the network being  
20 provided by coaxial cable having at least one branch which is divided at a node into at least two sub-branches in a path direction extending away from the server, and a two-way amplifier being provided at the node to amplify/maintain the signal level of signals passing from the sub-branches to the branch in addition to the signal level of signals travelling from the branch to the sub-branches, the  
25 system being operable to transmit a signal from at least one of the devices to the server generally at the same time as a signal is transmitted from the server to the devices.
53. A networked system comprising a server and a plurality of devices at different

locations connected to the server by a network, at least part of the network being provided by coaxial cable having at least one branch which is divided at a node into at least two sub-branches in a path direction extending away from the server, and a two-way amplifier being provided at the node to amplify/maintain the signal level of signals passing from the sub-branches to the branch in addition to the signal level of signals travelling from the branch to the sub-branches, the system being arranged to transmit the signals from the server to the devices on different channels allocated according to the device, and to transmit signals from each device to the server on the same channel as is used for transmission from the server to that device.

54. A system for distributing television/video/radio/audio signals to different locations, the system comprising means for receiving analogue television or radio signals or for generating analogue video or audio signals, means for converting the analogue signals to digital signals and supplying the digital signals to a server, a plurality of receivers each at a respective one of said locations, and a network connecting the server to the receivers, each receiver including means for converting the digital signals to analogue signals for supply to a picture/sound reproduction means.

55. A system according to claim 54, wherein the analogue to digital converting means includes means for compressing the digital signals to a standard compressed digital format, and each digital to analogue converting means includes means for decompressing the digital signals.

56. A system according to claim 54 or 55, wherein the receiving means includes an aerial for receiving modulated terrestrial analogue television/radio signals for a plurality of programmes, and means for demodulating the modulated signal for at least one of the programmes.

57. A system according to any of claims 54 to 56, wherein the receiving means includes a satellite receiver for receiving scrambled and multiplexed satellite

analogue television signals for a plurality of programmes, and means for descrambling and demultiplexing the signal for at least one of the programmes.

58. A system according to any of claims 54 to 57, wherein the receiving means includes a satellite receiver for receiving scrambled and multiplexed satellite analogue television signals for a plurality of programmes, means for descrambling and demultiplexing the signal for at least one of the programmes to produce an intermediate signal, means for modulating an RF signal with the intermediate signal, and means for demodulating the modulated RF signal.
59. A system for distributing television/video/radio/audio signals to different locations, the system comprising a reception and production centre for receiving analogue television or radio signals or for generating analogue video or audio signals, a processor for converting the analogue signals to digital signals and supplying the digital signals to a server, a plurality of receivers each at a respective one of said locations, and a network connecting the server to the receivers, each receiver including a digital to analogue convertor for converting the digital signals to analogue signals for supply to an output device.
60. A system for distributing television/video/radio/audio signals to different locations, substantially as described particularly with reference to, or as illustrated in Figures 11 and 18 to 21 of the drawings.
61. A method of distributing television/video/radio/audio signals to different locations, comprising: receiving analogue television or radio signals or generating analogue video or audio signals, converting the analogue signals to digital signals, supplying the digital signals to a server, distributing the digital signals over a network to a plurality of receivers each at a respective one of said locations, and, at each receiver, converting the digital signal to an analogue signal and reproducing a picture/sound from the analogue signal.
62. A system or method according to any of claims 32 to 61, wherein the different

locations are different rooms in a hotel.

63. A control system for a television set, comprising a first circuit on at least one first circuit board for receiving a digital video signal from a network and for decoding the digital video signal to produce a decoded video signal for supply to a standard video interface of the television set, the first circuit also being operable to receive control instructions from the network and/or from a user interface and to generate a generic control signal therefrom, the control system further comprising a second circuit provided on at least one second circuit board that is specific to the type of the television set, the second circuit being operable to receive the generic control signal from the first circuit and to convert the generic control signal into a specific control signal for supply to a control interface of the television set so as to control the television set in accordance with the control instructions.
64. A system according to claim 63, wherein said one second circuit board is installed in a slot on a main circuit board of the television set inside the housing of the television set, and said one first circuit board is installed inside a housing distinct from the television set housing.
65. A system according to claim 63, wherein said one first circuit board and said one second circuit board are installed in first and second slots, respectively, on a main circuit board of the television set inside the housing of the television set.
66. A system according to claim 63, wherein said one second circuit board is installed in a first slot on a main circuit board of the television set inside the housing of the television set, and said one first circuit board is installed in a second slot on said one second circuit board or one of the second circuit boards.
67. A control system for a television set, substantially as described particularly with reference to, or as illustrated in Figure 13, 14 or 15 of the drawings.

68. A combination of a first circuit on at least one first circuit board and a second circuit on at least one second circuit board for controlling a television set, the first circuit having means for receiving a digital video signal from a network and to for decoding the digital video signal to produce a decoded video signal for supply to a standard video interface of the television set, the first circuit further comprising means for receiving control instructions from the network and/or from a user interface and for generating a generic control signal therefrom, the second circuit having means for receiving the generic control signal from the first circuit and for converting the generic control signal into a specific control signal having a different format than the generic control signal, for supply to a control interface of a television set so as to control the television set in accordance with the control instructions.
69. A combination according to claim 68, wherein both said one first circuit board and said one second circuit board have means for installation in respective first and second slots on a main circuit board of the television set.
70. A combination according to claim 68, wherein said one second circuit board has means for installation in a first slot on a main circuit board of the television set, and said one first circuit board has means for installation in a second slot on said one first circuit board or one of the first circuit boards.
71. A combination of a first circuit on at least one first circuit board and a second circuit on at least one second circuit board for controlling a television set, the first circuit having a first receiver for receiving a digital video signal from a network and for decoding the digital video signal to produce a decoded video signal for supply to a standard video interface of the television set, the first circuit further comprising a processor for receiving control instructions from the network and/or from a user interface and for generating a generic control signal therefrom, the second circuit having a second receiver for receiving the generic control signal from the first circuit and for converting the generic control signal into a specific control signal having a different format than the generic control

signal, for supply to a control interface of a television set so as to control the television set in accordance with the control instructions.

72. A range of circuit boards for controlling a television set, each circuit board of the range comprising means for connection to a generic circuit board, each circuit board of the range comprising means for receiving a generic control signal, based on control instructions received from a network and/or from a user interface, from the generic circuit board, and means for converting the generic control signal into a specific control signal having a different format than the generic control signal, and means for supplying the specific control signals to a control interface of the television set so as to control the television set in accordance with the control instructions.
73. A range of circuit boards according to claim 62, wherein the formats of the specific control signals are all different for different control boards of the range.
74. A range of circuit boards according to claim 72 or 73, wherein each circuit board of the range has a slot for installation of the generic circuit board therein.
75. A range of circuit boards for controlling a television set, each circuit board of the range comprising a connection to a generic circuit board, each circuit board of the range comprising a receiver for receiving a generic control signal, based on control instructions received from a network and/or from a user interface, from the generic circuit board, and a processor for converting the generic control signal into a specific control signal having a different format than the generic control signal, and for supplying the specific control signals to a control interface of the television set so as to control the television set in accordance with the control instructions.
76. A range of circuit boards, substantially as described particularly with reference to, or as illustrated in Figures 13, 14, 15A or 15B of the drawings.

77. A method of configuring a control system according to any of claims 63 to 67 for a particular television set, the method comprising selecting, from a collection of such second circuit boards for different types of television sets, a circuit board that is specific to the type of the particular television set, and installing the selected second circuit board in conjunction with such a first circuit board.
78. A method of configuring a control system for a television set, substantially as described particularly with reference to, or as illustrated in Figure 13, 14, 15A, or 15B of the drawings.
79. A networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective device address, each second connector part having a respective connector address, the server storing the device addresses and, for each device address a corresponding connector address, and each device being operable to:- (a) supply its device address to the server and requesting the corresponding connector address, (b) receive the corresponding connector address from the server, (c) request the connector address from the respective connector, (d) receive the connector address from the connector, (e) compare the connector addresses received from the server and the connector, and (f) perform different processes in dependence upon whether or not the compared addresses match.
80. A system according to claim 79, wherein each device is operable to:- (a) supply its device address to the server and requesting the corresponding connector address, (b) receive the corresponding connector address from the server, (c) request the connector address from the respective connector, (d) receive the connector address from the connector, (e) compare the connector addresses received from the server and the connector, and (f) perform different processes in dependence upon whether or not the compared addresses match

upon powering-up of the device.

81. A system according to claim 80, wherein each device is operable, if the compared addresses do match, to power-up to a fully-operational state.
82. A system according to claim 80 or 81, wherein each device is operable, if the compared addresses do not match, to power-up to a partly-operational state.
83. A system according to any of claims 79 to 82, wherein each device is operable, if the compared addresses do not match, to notify the server that the compared addresses do not match.
84. A networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective connector address, the system comprising means for storing the device addresses and, for each device address, a corresponding connector address, and means for comparing, for a given device address, whether the stored corresponding connector address matches the connector address of the second connector part adjacent the device, the system being arranged to perform different processes depending on the result of the comparison.
85. A networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective connector address, the system comprising means for storing the device addresses and, for each device address, a corresponding connector address, and means for comparing, for a given second connector part, whether the stored corresponding device address matches the device address of the device adjacent the second connector part, the system being arranged to perform

different processes depending on the result of the comparison.

86. A networked system according to claims 84 or 85, wherein the comparing means forms part of the server.
87. A networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective connector address, the system comprising a memory for storing the device addresses and, for each device address, a corresponding connector address, and a processor for comparing, for a given device address, whether the stored corresponding connector address matches the connector address of the second connector part adjacent the device, the system being arranged to perform different processes depending on the result of the comparison.
88. A networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective connector address, the system comprising a memory for storing the device addresses and, for each device address, a corresponding connector address, and a processor for comparing, for a given second connector part, whether the stored corresponding device address matches the device address of the device adjacent the second connector part, the system being arranged to perform different processes depending on the result of the comparison.
89. A system according to any of claims 79 to 86 and also falling within the scope of any of claims 1 to 13, 22 to 28, 35 to 47, 52 to 59 and 62 to 67.
90. A method of operation of a device in a networked system comprising a server

and a plurality of such devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective device address, each second connector part having a respective connector address, and the server storing the device addresses and, for each device address a corresponding connector address, the method comprising (a) the device supplying its device address to the server and requesting the corresponding connector address, (b) the device receiving the corresponding connector address from the server, (c) the device requesting the connector address from the respective connector, (d) the device receiving the connector address from the connector, (e) the device comparing the connector addresses received from the server and the connector, and (f) the device performing different processes in dependence upon whether or not the compared addresses match.

91. A method of operation of a networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective connector address, the method comprising (a) storing pairs of addresses, wherein each pair comprises a device address and a corresponding connector address, (b) comparing, for a given device address, whether the stored corresponding connector address matches the connector address of the second connector part adjacent the device, and (c) performing different processes depending on the result of the comparison.

92. A method of operation of a networked system comprising a server and a plurality of devices connected to the server by a network, the network including, adjacent each device, a releasable connector having a first connector part connected to the respective device and a second connector part connected to the remainder of the network, each device having a respective device address, the method comprising (a) storing pairs of addresses, wherein each pair comprises a device address and a

corresponding connector address, (b) comparing, for a given second connector part, whether the stored corresponding device address matches the device address of the device adjacent the second connector part, and (c) performing different processes depending on the result of the comparison.

- 5    93.    A method according to claim 91 or 92, wherein the addresses are compared by the server.
94.    A device for use in a networked system comprising a server and a plurality of such devices connectable to the server by a network via respective connectors, the device having a respective device address, the device comprising (a) means  
10    for supplying its device address to the server and requesting a corresponding connector address stored in the server, (b) means for receiving the corresponding connector address from the server, (c) means for requesting the connector address from a connector for the device, (d) means for receiving the connector address from the respective connector, (e) means for comparing the connector  
15    addresses received from the server and the connector, and (f) means for performing different processes in dependence upon whether or not the compared addresses match.
95.    A device according to claim 94, wherein the device comprises means for performing the functionality of the elements (a) to (f) upon powering up.
- 20    96.    A device according to claim 95, wherein the device has means for powering-up to a fully-operational state if the compared addresses do match.
97.    A device according to claim 95 or 96, wherein the device has means for powering-up to a partly-operational state if the compared addresses do not match.
- 25    98.    A device according to any of claims 94 to 97, wherein the device has means for notifying the server that the compared addresses do not match if the compared addresses do not match.

- 66 -

99. A device for use in a networked system comprising a server and a plurality of such devices connectable to the server by a network via respective connectors, the device having a respective device address, the device comprising (a) an transmitter for supplying its device address to the server and requesting a  
5 corresponding connector address stored in the server, (b) a receiver for receiving the corresponding connector address from the server, (c) an output device for requesting the connector address from a connector for the device, (d) an input device for receiving the connector address from the respective connector, (e) a comparator for comparing the connector addresses received from the server and  
10 the connector, and (f) a processor for performing different processes in dependence upon whether or not the compared addresses match.
100. A method of operation of a device in networked system substantially as described, particularly with reference to, or as illustrated in Figures 16 and 17.
101. A combination of a first circuit on at least on substantially as described,  
15 particularly with reference to, or as illustrated in Figures 13, 14, 15A, and 15B.

# INTERNATIONAL SEARCH REPORT

International Application No

PCT/GB 01/00533

## A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 H04N7/10 H04N7/173

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 H04N H04L

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EP0-Internal, WPI Data, PAJ, INSPEC

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category °	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	WO 00 08854 A (JEFFREY ROSS A) 17 February 2000 (2000-02-17) page 4, line 21 -page 6, line 5; figures 1,2 page 9, line 8 -page 10, line 21 page 16, line 1 - line 27 page 17, line 10 -page 18, line 14 ---	1-21, 31-33

☐ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

### ° Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

Date of the actual completion of the international search

19 October 2001

Date of mailing of the international search report

# INTERNATIONAL SEARCH REPORT

International application No.  
PCT/GB 01/00533

## Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:
  
2. ☐ Claims Nos.:  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
  
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

## Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
  
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
  
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
  
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1-53

### Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. Claims: 1-53

system for distributing digital video signals characterized by point-to-point communication between a server and a plurality of receivers

2. Claims: 54-62

system for distributing digital video signals adapted for the processing of analogue video signals

3. Claims: 63-78

control system for a television set

4. Claims: 79-101

communication protocol used by a server and a receiving device in a networked system
