Asserted Claims	Pugel '200
	Pugel '200 at Fig. 5:  *FIG. 5* 500 Pugel '200 at [0021]-[0023]: Each of the channel processors 130 comprises a mixer 132, a decimator/filter 134, a digital demodulator 136 and a transport processor 138. It will be appreciated by those skilled in

Page 1464 of 4862

Comcast, Ex. 1004, Part 2 of 3

Asserted Claims	Pugel '200
	the art that the digital demodulator 136 and transport processor 138 may be combined into a single integrated circuit known as a link IC. Each of the mixers 132 mixes the digital signal S3 with a respective numerically controlled oscillator (NCO) signal to produce respective in-phase I and quadrature Q signal components, which are coupled to the respective decimator/filters 134. The respective NCO frequency is selected to derotate a desired signal or channel. Each mixer 132 operates to perform a frequency rotation function, whereby the selected channel is rotated to baseband from the undersampled digital signal S3. This may be accomplished using a numerical table to extract (or rotate) the desired channel frequency from the digital signal comprising all available frequencies processed by the A/D converter 120. The decimator/filter 134 receives the respective in-phase I and quadrature Q components of the derotated and selected channel. The decimator/filter 134 processes these orthogonal components to extract the desired signal. Briefly, after the mixer 132 derotates the selected signal to baseband (i.e., by multiplying the signal by sine and cosine functions), non-desired channel energy is removed from the derotated signal. Specifically, given the exemplary embodiment whereby 16 channels are simultaneously processed, it is desired to retain only the channel energy associated with a specific desired channel. After filtering the derotated baseband signal to remove undesired channel energy, the remaining signal is decimated to remove excess energy associated with the desired channel. For example, since the sampling frequency of the A/D converter is 1.5 gigasamples per second, frequency components from zero to 750 MHz may be present. Those samples not associated with the (approximately) 24 MHz associated with a selected channel are unnecessary. The decimation process removes the unwanted samples. As will be appreciated by those skilled in the art, the 24 MHz associated with a selected channel is actually two 12 MHz channels due to the sine/cosine processing of the derotator or mixer 132. The resulting derotated, filtered, and decimated signal is then provided to the respective demodulator 136. Pugel '200 at [0044]:

Asserted Claims	Pugel '200
	At step 520, each of the channels of interest within the digitized and band-limited block of channels is derotated to produce a respective derotated stream providing the channel of interest. At step 525, each of the derotated streams is filtered to remove the channel energy of other channels (i.e., the channel energy associated with channels not to be processed by the particular channel processor 130). At step 530, each of the filtered and derotated streams is decimated to remove excess samples. At step 535, each of the decimated streams is demodulated to recover the respective carrier transport streams. As previously discussed, the carrier transport streams include indicia of stream identifier and sequence code for each packet or group of packets used to form, illustratively, an MPEG transport stream. Optionally, the transport streams include channel identification and time of transmission data. The functions of steps 520-540 are discussed in more detail above with respect to the channel processors 130 of the receiver 100 of FIG. 1. To the extent Pugel '200 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Pugel '200 alone or it would have been obvious to combine Pugel '200 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
16. The method of claim 14 wherein the step of combining comprises frequency translating the selected and extracted transponder channels to a variable frequency before combining.	Pugel '200 discloses, explicitly and/or inherently, wherein the step of combining comprises frequency translating the selected and extracted transponder channels to a variable frequency before combining. *See* claim 14, *supra*. *See, e.g.*: Pugel '200 at [0021]-[0023]: Each of the channel processors 130 comprises a mixer 132, a decimator/filter 134, a digital demodulator 136 and a transport processor 138. It will be appreciated by those skilled in

Asserted Claims	Pugel '200
	the art that the digital demodulator 136 and transport processor 138 may be combined into a single integrated circuit known as a link IC. Each of the mixers 132 mixes the digital signal S3 with a respective numerically controlled oscillator (NCO) signal to produce respective in-phase I and quadrature Q signal components, which are coupled to the respective decimator/filters 134. The respective NCO frequency is selected to derotate a desired signal or channel. Each mixer 132 operates to perform a frequency rotation function, whereby the selected channel is rotated to baseband from the undersampled digital signal S3. This may be accomplished using a numerical table to extract (or rotate) the desired channel frequency from the digital signal comprising all available frequencies processed by the A/D converter 120. The decimator/filter 134 receives the respective in-phase I and quadrature Q components of the derotated and selected channel. The decimator/filter 134 processes these orthogonal components to extract the desired signal. Briefly, after the mixer 132 derotates the selected signal to baseband (i.e., by multiplying the signal by sine and cosine functions), non-desired channel energy is removed from the derotated signal. Specifically, given the exemplary embodiment whereby 16 channels are simultaneously processed, it is desired to retain only the channel energy associated with a specific desired channel. After filtering the derotated baseband signal to remove undesired channel energy, the remaining signal is decimated to remove excess energy associated with the desired channel. For example, since the sampling frequency of the A/D converter is 1.5 gigasamples per second, frequency components from zero to 750 MHz may be present. Those samples not associated with the (approximately) 24 MHz associated with a selected channel are unnecessary. The decimation process removes the unwanted samples. As will be appreciated by those skilled in the art, the 24 MHz associated with a selected channel is actually two 12 MHz channels due to the sine/cosine processing of the derotator or mixer 132. The resulting derotated, filtered, and decimated signal is then provided to the respective demodulator 136. To the extent Pugel '200 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art

The resulting derotated, filtered, and decimated signal is then provided to the respective demodulator 136.

Asserted Claims	Pugel '200
	Pugel '200 at [0044]: At step 520, each of the channels of interest within the digitized and band-limited block of channels is derotated to produce a respective derotated stream providing the channel of interest. At step 525, each of the derotated streams is filtered to remove the channel energy of other channels (i.e., the channel energy associated with channels not to be processed by the particular channel processor 130). At step 530, each of the filtered and derotated streams is decimated to remove excess samples. At step 535, each of the decimated streams is demodulated to recover the respective carrier transport streams. As previously discussed, the carrier transport streams include indicia of stream identifier and sequence code for each packet or group of packets used to form, illustratively, an MPEG transport stream. Optionally, the transport streams include channel identification and time of transmission data. The functions of steps 520-540 are discussed in more detail above with respect to the channel processors 130 of the receiver 100 of FIG. 1. To the extent Pugel '200 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Pugel '200 alone or it would have been obvious to combine Pugel '200 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
35. The method of claim 14, further comprising converting the selected signal to an analog signal using a digital to analog converter prior to combining.	Pugel '200 discloses, explicitly and/or inherently, further comprising converting the selected signal to an analog signal using a digital to analog converter prior to combining. *See* claim 14, *supra*. To the extent Pugel '200 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Pugel '200 alone or it would have been obvious to combine Pugel '200 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.

Page 1474 of 4862

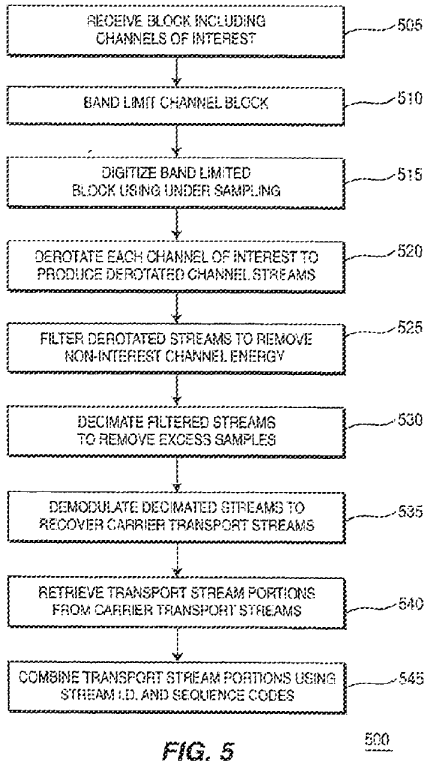
Asserted Claims	Pugel '200
36. The method of claim 14, wherein the combining is performed in the digital domain.	Pugel '200 discloses, explicitly and/or inherently, wherein the combining is performed in the digital domain. *See* claim 14, *supra*. *See, e.g.*: Pugel '200 at Abstract: An apparatus and method for simultaneously processing each of a plurality of carrier signals having data modulated thereon, wherein a complete data stream is formed by extracting at least portions of at least two of the modulated signals and combining the extracted portions. Each of the portions of the complete data stream comprises a plurality of packets having associated with them respective stream identification and sequence codes, where the stream identification identifies the complete bit stream to be formed, and the sequence codes identify the order or position within the complete bitstream that the associated data packets should be inserted. Pugel '200 at [0005]-[0006]: The invention comprises an apparatus and method for simultaneously processing each of a plurality of carrier signals having data modulated thereon, wherein a complete data stream is formed by extracting at least portions of at least two of the modulated signals and combining the extracted portions. Each of the portions of the complete data stream comprises a plurality of packets having associated with them respective stream identification and sequence codes, where the stream identification identifies the complete bit stream to be formed, and the sequence codes identify the order or position within the complete bitstream that the associated data packets should be inserted. An apparatus, in accordance with an embodiment of the present invention, comprises an analog to digital converter, for directly converting a plurality of carrier signals into a digital data stream; a plurality of channel processors, for simultaneously extracting from

Asserted Claims	Pugel '200
	the digital data stream data carried by respective carrier signals; and a processor, for combining at least portions of the data extracted from at least two carrier signals to produce a complete bitstream, the extracted data having associated with it stream identifier and sequence code information for determining, respectively, the complete bitstream corresponding to the extracted data and the sequence within the complete bitstream of the extracted data. Pugel '200 at [0046]: In one embodiment of the invention, only a subset of the received channels is processed. That is, to reduce costs and complexity within the receiver 100 of FIG. 1, two or more channel processors 130 are utilized. However, the number of channel processors 130 actually utilized is less than the number of channels present within output signal S3 of the A/D converter 120. In this embodiment, channel identifier and channel transmit time information is utilized to cause at least one of the channel processors 130 to selectively process different channels at different times. In this manner, the selected at least one channel processor is caused to "hop" between different channels such that all of the data necessary to reconstruct an initial bitstream may be retrieved utilizing less than a full complement of channel processors. Pugel '200 at Claim 1: 1. A method, comprising: converting a plurality of carrier signals into a digital data stream; extracting from said digital data stream, data carried by at least two carrier signals; and combining at least portions of data extracted from said at least two carrier signals to form a complete bitstream, said extracted data having associated with it stream identifier and sequence code information for, respectively, identifying the complete bitstream

Asserted Claims	Pugel '200
	corresponding to the extracted data and determining the position of the extracted data within the complete bitstream. To the extent Pugel '200 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Pugel '200 alone or it would have been obvious to combine Pugel '200 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
37. The method of claim 17, wherein frequency translating comprises using a digital mixer to apply a rotating phasor to the data samples to translate their frequency.	Pugel '200 discloses, explicitly and/or inherently, wherein frequency translating comprises using a digital mixer to apply a rotating phasor to the data samples to translate their frequency. *See* claim 17, *supra*. *See, e.g.*: Pugel '200 at [0021]-[0023]: Each of the channel processors 130 comprises a mixer 132, a decimator/filter 134, a digital demodulator 136 and a transport processor 138. It will be appreciated by those skilled in the art that the digital demodulator 136 and transport processor 138 may be combined into a single integrated circuit known as a link IC. Each of the mixers 132 mixes the digital signal S3 with a respective numerically controlled oscillator (NCO) signal to produce respective in-phase I and quadrature Q signal components, which are coupled to the respective decimator/filters 134. The respective NCO frequency is selected to derotate a desired signal or channel. Each mixer 132 operates to perform a frequency rotation function, whereby the selected channel is rotated to baseband from the undersampled digital signal S3. This may be accomplished using a numerical table to extract (or rotate) the desired channel frequency from the digital signal comprising all available frequencies processed by the A/D converter 120.

Asserted Claims	Pugel '200
	The decimator/filter 134 receives the respective in-phase I and quadrature Q components of the derotated and selected channel. The decimator/filter 134 processes these orthogonal components to extract the desired signal. Briefly, after the mixer 132 derotates the selected signal to baseband (i.e., by multiplying the signal by sine and cosine functions), non-desired channel energy is removed from the derotated signal. Specifically, given the exemplary embodiment whereby 16 channels are simultaneously processed, it is desired to retain only the channel energy associated with a specific desired channel. After filtering the derotated baseband signal to remove undesired channel energy, the remaining signal is decimated to remove excess energy associated with the desired channel. For example, since the sampling frequency of the A/D converter is 1.5 gigasamples per second, frequency components from zero to 750 MHz may be present. Those samples not associated with the (approximately) 24 MHz associated with a selected channel are unnecessary. The decimation process removes the unwanted samples. As will be appreciated by those skilled in the art, the 24 MHz associated with a selected channel is actually two 12 MHz channels due to the sine/cosine processing of the derotator or mixer 132. The resulting derotated, filtered, and decimated signal is then provided to the respective demodulator 136. To the extent Pugel '200 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Pugel '200 alone or it would have been obvious to combine Pugel '200 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
38. The method of claim 14, further comprising frequency translating the digitized broadband signal prior to selecting and extracting transponder signal.	Pugel '200 discloses, explicitly and/or inherently, further comprising frequency translating the digitized broadband signal prior to selecting and extracting transponder signal. *See* claims 14, 17, *supra*. *See, e.g.*: Pugel '200 at [0021]-[0023]:

Asserted Claims	Pugel '200
	Each of the channel processors 130 comprises a mixer 132, a decimator/filter 134, a digital demodulator 136 and a transport processor 138. It will be appreciated by those skilled in the art that the digital demodulator 136 and transport processor 138 may be combined into a single integrated circuit known as a link IC. Each of the mixers 132 mixes the digital signal S3 with a respective numerically controlled oscillator (NCO) signal to produce respective in-phase I and quadrature Q signal components, which are coupled to the respective decimator/filters 134. The respective NCO frequency is selected to derotate a desired signal or channel. Each mixer 132 operates to perform a frequency rotation function, whereby the selected channel is rotated to baseband from the undersampled digital signal S3. This may be accomplished using a numerical table to extract (or rotate) the desired channel frequency from the digital signal comprising all available frequencies processed by the A/D converter 120. The decimator/filter 134 receives the respective in-phase I and quadrature Q components of the derotated and selected channel. The decimator/filter 134 processes these orthogonal components to extract the desired signal. Briefly, after the mixer 132 derotates the selected signal to baseband (i.e., by multiplying the signal by sine and cosine functions), non-desired channel energy is removed from the derotated signal. Specifically, given the exemplary embodiment whereby 16 channels are simultaneously processed, it is desired to retain only the channel energy associated with a specific desired channel. After filtering the derotated baseband signal to remove undesired channel energy, the remaining signal is decimated to remove excess energy associated with the desired channel. For example, since the sampling frequency of the A/D converter is 1.5 gigasamples per second, frequency components from zero to 750 MHz may be present. Those samples not associated with the (approximately) 24 MHz associated with a selected channel are unnecessary. The decimation process removes the unwanted samples. As will be appreciated by those skilled in the art, the 24 MHz associated with a selected channel is actually two 12 MHz channels due to the sine/cosine processing of the derotator or mixer 132. The resulting derotated, filtered, and decimated signal is then provided to the respective demodulator 136.



Asserted Claims	Pugel '200
	To the extent Pugel '200 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Pugel '200 alone or it would have been obvious to combine Pugel '200 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
39. The method of claim 38, wherein frequency translating comprises translating the original digitized broadband signal to locate a selected transponder channel at baseband.	Pugel '200 discloses, explicitly and/or inherently, wherein frequency translating comprises translating the original digitized broadband signal to locate a selected transponder channel at baseband. *See* claim 38, *supra*. *See, e.g.*: Pugel '200 at [0021]-[0023]: Each of the channel processors 130 comprises a mixer 132, a decimator/filter 134, a digital demodulator 136 and a transport processor 138. It will be appreciated by those skilled in the art that the digital demodulator 136 and transport processor 138 may be combined into a single integrated circuit known as a link IC. Each of the mixers 132 mixes the digital signal S3 with a respective numerically controlled oscillator (NCO) signal to produce respective in-phase I and quadrature Q signal components, which are coupled to the respective decimator/filters 134. The respective NCO frequency is selected to derotate a desired signal or channel. Each mixer 132 operates to perform a frequency rotation function, whereby the selected channel is rotated to baseband from the undersampled digital signal S3. This may be accomplished using a numerical table to extract (or rotate) the desired channel frequency from the digital signal comprising all available frequencies processed by the A/D converter 120. The decimator/filter 134 receives the respective in-phase I and quadrature Q components of the derotated and selected channel. The decimator/filter 134 processes these orthogonal components to extract the desired signal. Briefly, after the mixer 132 derotates the selected

Asserted Claims	Pugel '200
	signal to baseband (i.e., by multiplying the signal by sine and cosine functions), non-desired channel energy is removed from the derotated signal. Specifically, given the exemplary embodiment whereby 16 channels are simultaneously processed, it is desired to retain only the channel energy associated with a specific desired channel. After filtering the derotated baseband signal to remove undesired channel energy, the remaining signal is decimated to remove excess energy associated with the desired channel. For example, since the sampling frequency of the A/D converter is 1.5 gigasamples per second, frequency components from zero to 750 MHz may be present. Those samples not associated with the (approximately) 24 MHz associated with a selected channel are unnecessary. The decimation process removes the unwanted samples. As will be appreciated by those skilled in the art, the 24 MHz associated with a selected channel is actually two 12 MHz channels due to the sine/cosine processing of the derotator or mixer 132. The resulting derotated, filtered, and decimated signal is then provided to the respective demodulator 136. To the extent Pugel '200 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Pugel '200 alone or it would have been obvious to combine Pugel '200 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
40. The method of claim 14, further comprising maintaining a channel translation table at the outdoor unit, the channel translation table specifying assigned frequency slots for transponder channels in the composite signal.	Pugel '200 discloses, explicitly and/or inherently, further comprising maintaining a channel translation table at the outdoor unit, the channel translation table specifying assigned frequency slots for transponder channels in the composite signal. *See* claim 14, *supra*. *See, e.g.*: Pugel '200 at [0033]-[0034]:

Asserted Claims	Pugel '200
42. The method of claim 14, wherein selecting and extracting comprises low-pass filtering the translated digitized broadband signal thereby substantially removing signal information from non-selected transponder channels.	Pugel '200 discloses, explicitly and/or inherently, wherein selecting and extracting comprises low-pass filtering the translated digitized broadband signal thereby substantially removing signal information from non-selected transponder channels. *See* claim 14, *supra*. *See, e.g.*: Pugel '200 at Fig. 5:

Asserted Claims	Pugel '200
	 *FIG. 5* Pugel '200 at [0021]-[0023]: Each of the channel processors 130 comprises a mixer 132, a decimator/filter 134, a digital demodulator 136 and a transport processor 138. It will be appreciated by those skilled in the art that the digital demodulator 136 and transport processor 138 may be combined into a single integrated circuit known as a link IC.

Asserted Claims	Pugel '200
	Each of the mixers 132 mixes the digital signal S3 with a respective numerically controlled oscillator (NCO) signal to produce respective in-phase I and quadrature Q signal components, which are coupled to the respective decimator/filters 134. The respective NCO frequency is selected to derotate a desired signal or channel. Each mixer 132 operates to perform a frequency rotation function, whereby the selected channel is rotated to baseband from the undersampled digital signal S3. This may be accomplished using a numerical table to extract (or rotate) the desired channel frequency from the digital signal comprising all available frequencies processed by the A/D converter 120. The decimator/filter 134 receives the respective in-phase I and quadrature Q components of the derotated and selected channel. The decimator/filter 134 processes these orthogonal components to extract the desired signal. Briefly, after the mixer 132 derotates the selected signal to baseband (i.e., by multiplying the signal by sine and cosine functions), non-desired channel energy is removed from the derotated signal. Specifically, given the exemplary embodiment whereby 16 channels are simultaneously processed, it is desired to retain only the channel energy associated with a specific desired channel. After filtering the derotated baseband signal to remove undesired channel energy, the remaining signal is decimated to remove excess energy associated with the desired channel. For example, since the sampling frequency of the A/D converter is 1.5 gigasamples per second, frequency components from zero to 750 MHz may be present. Those samples not associated with the (approximately) 24 MHz associated with a selected channel are unnecessary. The decimation process removes the unwanted samples. As will be appreciated by those skilled in the art, the 24 MHz associated with a selected channel is actually two 12 MHz channels due to the sine/cosine processing of the derotator or mixer 132. The resulting derotated, filtered, and decimated signal is then provided to the respective demodulator 136. Pugel '200 at [0021]-[0023]: Each of the channel processors 130 comprises a mixer 132, a decimator/filter 134, a digital demodulator 136 and a transport processor 138. Asserted Claims	Pugel '200
	At step 520, each of the channels of interest within the digitized and band-limited block of channels is derotated to produce a respective derotated stream providing the channel of interest. At step 525, each of the derotated streams is filtered to remove the channel energy of other channels (i.e., the channel energy associated with channels not to be processed by the particular channel processor 130). At step 530, each of the filtered and derotated streams is decimated to remove excess samples. At step 535, each of the decimated streams is demodulated to recover the respective carrier transport streams. As previously discussed, the carrier transport streams include indicia of stream identifier and sequence code for each packet or group of packets used to form, illustratively, an MPEG transport stream. Optionally, the transport streams include channel identification and time of transmission data. The functions of steps 520-540 are discussed in more detail above with respect to the channel processors 130 of the receiver 100 of FIG. 1. To the extent Pugel '200 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Pugel '200 alone or it would have been obvious to combine Pugel '200 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.

INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,130,576 in view of Williams '419

U.S. Patent No. 6,134,419 ("Williams '419")[2] was filed on January 20, 1998 and issued on October 17, 2000. Williams '419 is a continuation-in-part of and claims priority to U.S. Application No. 08/787,336 filed on January 27, 1997. Williams '419 therefore qualifies as prior art to the '576 patent under, at least, (pre-AIA) 35 U.S.C. § 102(a) and/or (e). For the reasons listed below, Williams '419 invalidates the asserted claims of the '576 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix A, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Williams '419
14[pre] 14. A method of communicating a plurality of transponder signals from a satellite outdoor unit (ODU) that receives a plurality of satellite broadband signals to an integrated receiver decoder (IRD) over a single cable connected to the ODU, the method comprising the steps of:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Williams '419 discloses, explicitly and/or inherently, a method of communicating a plurality of transponder signals from a satellite outdoor unit (ODU) that receives a plurality of satellite broadband signals to an integrated receiver decoder (IRD) over a single cable connected to the ODU. *See, e.g.*:

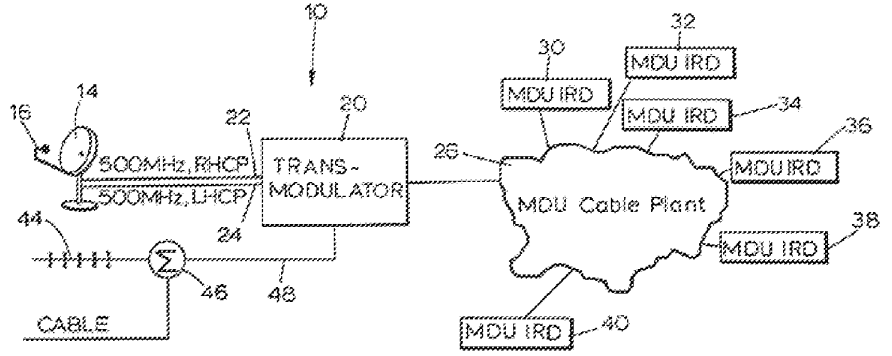
[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '576 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.

[2] Williams '419 was incorporated by reference in the '576 patent. *See* '576 patent at 2:8–25.

Asserted Claims	Williams '419
	Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 1:10–15: The present invention relates generally to signal distribution systems and, more particularly, to audio/visual/data signal distribution systems that distribute satellite signals typically in conjunction with standard terrestrial and/or cable signals to a plurality of individual receivers within one or more multiple dwelling units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between

Asserted Claims	Williams '419
	about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 2:41–55: Furthermore, the receiving antennas or dishes associated with land-based or satellite-based wireless signal distribution systems are typically large and cumbersome. For example, C-band satellite dishes are generally in the range of four to five feet in diameter and, therefore, require a large amount of operating space. As a result, it can be difficult, if not practically impossible, to install a receiving antenna for each individual unit within a multiple dwelling unit (MDU), such as an apartment, condominium or townhome complex. Reception of a particular satellite signal is made even more difficult in MDUs when, as is generally the case, some of the individual dwelling units therein do not have any walls or outside exposure facing the direction in which the receiving antenna must be pointed, or these dwelling units are shadowed by surrounding buildings or other obstructions. Williams '419 at 3:9–27:

Asserted Claims	Williams '419
	One system proposed by the European Telecommunications Standards Institute (ETSI) in the area of Satellite Master Antenna Television (SMATV) receives a QPSK modulated satellite television signal (which may be combined with terrestrial TV signals) and remodulates this signal according to a 64 quadrature amplitude modulation (64-QAM) technique. The SMATV system then sends this remodulated signal out over cable to one or more adjacent buildings. Likewise, U.S. Pat. No. 5,173,775 discloses a system that remodulates data portions of a satellite television signal from one modulation scheme to another, such as from FM to AM, for retransmission to subscribers. However, these systems do not specifically demonstrate how to propagate remodulated satellite signals and existing cable or terrestrial signals on the same cable line or other transmission channel in an efficient manner or demonstrate how to remodulate and broadcast a large number of transponder signals associated with one or more satellites over the same cable line or other transmission channel to one or more adjacent buildings. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 3:48–65:



Asserted Claims	Williams '419
	According to another aspect of the present invention, a signal distribution system that distributes first and second signals over a communication channel to a plurality of individual receivers includes a main receiver and a second receiver disposed at a local site for receiving the first and second signals, respectively. A transmodulator coupled to the main receiver transmodulates the first signal from a first modulation scheme, such as a QPSK modulation scheme, to a second modulation scheme, such as a 128-QAM modulation scheme, to produce a transmodulated third signal. A signal combiner coupled to the second receiver and to the transmodulator combines the transmodulated third signal at a first set of carrier frequency bands and the second signal at a second set of carrier frequency bands to produce a combined signal. A transmitter then transmits the combined signal over a cable or a wireless network in a manner capable of being received at the plurality of individual receivers. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47:

Asserted Claims	Williams '419
	According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 4:48–54: Accordingly, apartment dwellers, for instance within a MDU system of this invention, can still use the dual mode IRD of the present invention if they move within a currently available SFH system, and conversely, single family home dwellers can still use the dual mode IRD of the present invention if they move within a MDU system of this invention. Williams '419 at 5:55–6:7: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM signals. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a

Asserted Claims	Williams '419
	transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '419 at 7:1–8: Each of the IRDs 30-40 receives the 32, QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates at least a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. Williams '419 at 13:13–37: Furthermore, while the signal distribution system 10 is described herein as using a 128-QAM modulator 102, any other type of QAM modulator, such as an 8-QAM, 32-QAM, or higher order QAM modulator can be used to encode the decoded satellite signal, with the choice being dependent on how much frequency spectrum is available on a particular cable system and on how noisy the cable network tends to be which, in turn, drives the level of error protection required. In general, the higher the order of QAM encoding, the less frequency spectrum will be necessary to transmit the desired number (e.g., 32) satellite transponder signals (or other signals) over a cable network. However, the higher the order of QAM modulation, the more the transmodulated signals will be susceptible to noise while being transmitted over a cable network. Likewise, different ones of the transmodulator channels of FIG. 3 may transmodulate the received PM signal, i.e., the tuned transponder signal, using different modulation schemes. For example, a first set of the transmodulator channels may remodulate PM signals using a 128-QAM modulation technique, while a second set of transmodulator channels may use a 32-QAM modulation technique, a 64-QAM modulation technique, and so on. The choice of the modulation technique for any particular transmodulator channel may depend on, for example, the data rate of the PM signal being received, as well as other factors. Williams '419 at 13:38–54:

Asserted Claims	Williams '419
	Furthermore, as noted above, modulation techniques besides QAM can be used when transmodulating the decoded satellite signal. Other such modulation techniques may include, for example, any high rate digital modulation techniques such as VSB (vestigial side band), including 8-VSB, 16-VSB etc., or QAM with trellis-coded modulation. Other modulation techniques which may be developed in the future could similarly be used without departing from the spirit and scope of the present invention. In general, the choice of a modulation technique will be driven by the reduction in bandwidth which must be accomplished by the modulation technique and by the noise susceptibility of the modulation technique. If a different modulation technique is used, however, it is understood that a different type of cable encoder will be necessary to properly transmodulate the desired transponder signals (or other received signals) for propagation over the cable network 26. Williams '419 at 13:55–14:3: Likewise, it is understood that signals other than QPSK modulated signals can be received at the main signal receiver 14 (or other receiver) and transmodulated for delivery over the cable network 26 using the concepts described herein. In this situation, the particulars of the transmodulator 20 will change based on the type of modulation, carrier frequencies and transmission formats associated with these different received signals. It is considered that the use of an 8-PSK (phase shift keying) modulation scheme for encoding the satellite signal and a 16-QAM or higher order QAM (32-QAM, 64-QAM etc.) scheme for encoding the cable signal may be one useful combination. It is also considered that the use of a 16-QAM scheme for encoding the satellite signal and a 32-QAM or higher order QAM scheme for encoding the cable signal may be another useful combination. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of

Asserted Claims	Williams '419
	the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 1:

	program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one

Asserted Claims	Williams '419
	of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 4:48–54: Accordingly, apartment dwellers, for instance within a MDU system of this invention, can still use the dual mode IRD of the present invention if they move within a currently available SFH system, and conversely, single family home dwellers can still use the dual mode IRD of the present invention if they move within a MDU system of this invention. Williams '419 at 4:55–61: In a still further aspect of this invention, an MDU adapter enables a presently available IRD used within a current signal distribution system for SFHs (SFH IRD), to be compatible with a signal distribution system for MDUs of this invention. The MDU adapter demodulates a selected one of the received MDU network signals and modulates the selected signal in a manner compatible with the SFH IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the

Asserted Claims	Williams '419
	transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:1–8: Each of the IRDs 30-40 receives the 32, QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates at least a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. Williams '419 at 8:31–41: The L-band RHCP and LHCP signals (16 each) are linked to a set of up to 32 transmodulator channels, each of which includes a tuner 54, a satellite decoder 56, a packetizer 58, a cable encoder 60, and an upconverter 62. Each transmodulator channel decodes and transmodulates one of the 32 transponder signals associated with the downlink signal in essentially the same manner and, as a result, the operation of only one of the 32 transmodulator channels will be described herein. It should be understood that a greater or lesser number of transmodulator channels may alternatively be provided. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band.

Asserted Claims	Williams '419
	Williams '419 at 9:56–67: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. The control unit 72 may control, for example, tuning parameters, such as the output frequencies of the tuners 54 and may select the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-

Asserted Claims	Williams '419
	S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 1:  FIG. 1 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
14[b] in the ODU, digitizing the plurality of satellite broadband signals, selecting and extracting a plurality of transponder signals from the received satellite broadband signals, wherein the selecting is	Williams '419 discloses, explicitly and/or inherently, in the ODU, digitizing the plurality of satellite broadband signals, selecting and extracting a plurality of transponder signals from the received satellite broadband signals, wherein the selecting is responsive to the transponder request signals. *See, e.g.:*

Asserted Claims	Williams '419
responsive to the transponder request signals;	Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc.

Asserted Claims	Williams '419
	Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 6:8–27:

Asserted Claims	Williams '419
	The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 6:52–67: Preferably, the transmodulator 20 transmodulates the two 500 MHz-wide QPSK-modulated downlink signals into a 128-QAM-modulated signal having 32, 6 MHz-wide channels, wherein each of the 6 MHz-wide channels corresponds to one of the 32 original transponder signals. The transmodulator 20 may then place each of these 32, 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate the received satellite signals. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '419 at 7:1–8: Each of the IRDs 30-40 receives the 32, QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates at

Asserted Claims	Williams '419
	least a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:56–67: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. The control unit 72 may control, for example, tuning parameters, such as the output frequencies of the tuners 54 and may select the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if

Asserted Claims	Williams '419
	desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:28–33: After the control unit 72 identifies all of the empty or unused frequency bands, this information is preferably stored in non-volatile memory. Operator selection (e.g., by means of a keypad) may also be utilized to select or de-select frequency bands, either alone or in conjunction with an automated system. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
14[c] combining extracted selected transponder signals into a composite signal;	Williams '419 discloses, explicitly and/or inherently, combining extracted selected transponder signals into a composite signal. *See, e.g.*: Williams '419 at Abstract:

Asserted Claims	Williams '419
	A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 4:13–32:

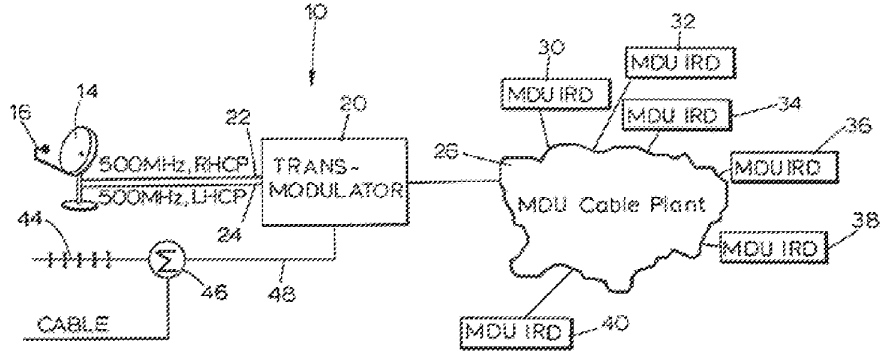
Asserted Claims	Williams '419
	According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 4:48–54: Accordingly, apartment dwellers, for instance within a MDU system of this invention, can still use the dual mode IRD of the present invention if they move within a currently

Asserted Claims	Williams '419
	available SFH system, and conversely, single family home dwellers can still use the dual mode IRD of the present invention if they move within a MDU system of this invention. Williams '419 at 5:25–40: By the way of example only, the signal distribution system of the present invention is described herein as redistributing a broadband Ku-band satellite signal (comprising up to 32, QPSK-modulated transponder signals transmitted from one or more satellites at a carrier frequency band centered around approximately 12.45 GHz) to receiver units within an MDU. It is understood however, that the signal distribution system of the present invention can be used to redistribute any other type of satellite or land-based wireless signal. The term program multiplex (PM) signal is used herein to describe any single or multiplex of purely visual (such as video), purely audio, or purely data signals as well as a signal comprising any combination of audio, visual, data or other signals including, for example, television signals, digital data signals, etc. Williams '419 at 7:9–36: Referring now to FIG. 2, representative methods of combining the transmodulated transponder signals along with terrestrial signals on the cable network 26 are illustrated. The left-most column of FIG. 2 illustrates a previously known method of placing QPSK-modulated signals along with terrestrial signals on a cable network. According to this scheme, all existing terrestrial signals (including cable TV signals) are distributed at, for example, VHF and UHF carrier frequencies below 950 MHz while one of the 500 MHz-wide QPSK-modulated signals (associated with either the LHCP or the RHCP component of the satellite signal) is placed directly on the cable network at the unused band between about 950 MHz and 1450 MHz. A major problem with this configuration is that only the RHCP or the LHCP transponder signals can be placed on a standard cable network at any given time which, in turn, prevents IRDs within an MDU from decoding or receiving channels associated with the other of the LHCP or the RHCP transponder signals. While this problem can be overcome by running two cable lines throughout an MDU or by utilizing a high frequency cable plant capable of approximately 2 GHz or greater

Asserted Claims	Williams '419
	bandwidth, these solutions require additional equipment and expense and are not adaptable to most existing cable plants now in use. Furthermore, the signals provided at the 950 MHz to 1450 MHz band can be severely degraded by the cable plant due to the poor high frequency propagation properties of many existing cable plants, especially older cable plants. Williams '419 at 7:37–46: The three right-most columns of FIG. 2 illustrate methods of combining the 32, 6 MHz-wide, 128-QAM-modulated signals with existing terrestrial signals on the cable network 26. The second left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals in sequence at a band between about 806 MHz and 998 MHz directly above the common CATV channels. This configuration can be used with higher grade cable networks that propagate signals at up to 1000 MHz without significant degradation. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art

Asserted Claims	Williams '419
	in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
14[d] transmitting the composite signal over the single cable from the ODU to the IRDs, wherein the modulation of the transponder signal is not altered by the steps of selecting, combining, and transmitting.	Williams '419 discloses, explicitly and/or inherently, transmitting the composite signal over the single cable from the ODU to the IRDs, wherein the modulation of the transponder signal is not altered by the steps of selecting, combining, and transmitting. *See, e.g.*: Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 1:10–15: The present invention relates generally to signal distribution systems and, more particularly, to audio/visual/data signal distribution systems that distribute satellite signals

Asserted Claims	Williams '419
	typically in conjunction with standard terrestrial and/or cable signals to a plurality of individual receivers within one or more multiple dwelling units. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a



Asserted Claims	Williams '419
	transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 4:48–54: Accordingly, apartment dwellers, for instance within a MDU system of this invention, can still use the dual mode IRD of the present invention if they move within a currently available SFH system, and conversely, single family home dwellers can still use the dual mode IRD of the present invention if they move within a MDU system of this invention. Williams '419 at 4:55–61: In a still further aspect of this invention, an MDU adapter enables a presently available IRD used within a current signal distribution system for SFHs (SFH IRD), to be compatible with a signal distribution system for MDUs of this invention. The MDU adapter demodulates a selected one of the received MDU network signals and modulates the selected signal in a manner compatible with the SFH IRD. Williams '419 at 5:55–6:7:

Asserted Claims	Williams '419
	The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM signals. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '419 at 6:52–67: Preferably, the transmodulator 20 transmodulates the two 500 MHz-wide QPSK-modulated downlink signals into a 128-QAM-modulated signal having 32, 6 MHz-wide channels, wherein each of the 6 MHz-wide channels corresponds to one of the 32 original transponder signals. The transmodulator 20 may then place each of these 32, 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate the received satellite signals. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these

Asserted Claims	Williams '419
	signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 13:13–37: Furthermore, while the signal distribution system 10 is described herein as using a 128-QAM modulator 102, any other type of QAM modulator, such as an 8-QAM, 32-QAM, or higher order QAM modulator can be used to encode the decoded satellite signal, with the choice being dependent on how much frequency spectrum is available on a particular cable system and on how noisy the cable network tends to be which, in turn, drives the level of error protection required. In general, the higher the order of QAM encoding, the less frequency spectrum will be necessary to transmit the desired number (e.g., 32) satellite transponder signals (or other signals) over a cable network. However, the higher the order of QAM modulation, the more the transmodulated signals will be susceptible to noise while being transmitted over a cable network. Likewise, different ones of the transmodulator channels of FIG. 3 may transmodulate the received PM signal, i.e., the tuned transponder signal, using different modulation schemes. For example, a first set of the transmodulator channels may remodulate PM signals using a 128-QAM modulation technique, while a second set of transmodulator channels may use a 32-QAM modulation technique, a 64-QAM modulation technique, and so on. The choice of the modulation technique for any particular transmodulator channel may depend on, for example, the data rate of the PM signal being received, as well as other factors. Williams '419 at 13:38–54:

Asserted Claims	Williams '419
	Furthermore, as noted above, modulation techniques besides QAM can be used when transmodulating the decoded satellite signal. Other such modulation techniques may include, for example, any high rate digital modulation techniques such as VSB (vestigial side band), including 8-VSB, 16-VSB etc., or QAM with trellis-coded modulation. Other modulation techniques which may be developed in the future could similarly be used without departing from the spirit and scope of the present invention. In general, the choice of a modulation technique will be driven by the reduction in bandwidth which must be accomplished by the modulation technique and by the noise susceptibility of the modulation technique. If a different modulation technique is used, however, it is understood that a different type of cable encoder will be necessary to properly transmodulate the desired transponder signals (or other received signals) for propagation over the cable network 26. Williams '419 at 13:55–14:3: Likewise, it is understood that signals other than QPSK modulated signals can be received at the main signal receiver 14 (or other receiver) and transmodulated for delivery over the cable network 26 using the concepts described herein. In this situation, the particulars of the transmodulator 20 will change based on the type of modulation, carrier frequencies and transmission formats associated with these different received signals. It is considered that the use of an 8-PSK (phase shift keying) modulation scheme for encoding the satellite signal and a 16-QAM or higher order QAM (32-QAM, 64-QAM etc.) scheme for encoding the cable signal may be one useful combination. It is also considered that the use of a 16-QAM scheme for encoding the satellite signal and a 32-QAM or higher order QAM scheme for encoding the cable signal may be another useful combination. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of

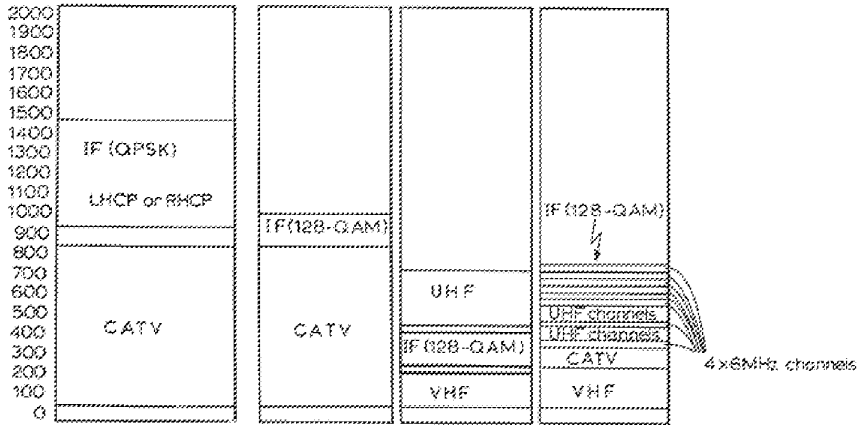
Asserted Claims	Williams '419
	the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 1:

Asserted Claims	Williams '419
	 FIG. 1 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
15. The method of claim 14 wherein the step of selecting and extracting a transponder signal comprises the step of: filtering a transponder signal with a band pass filter having a bandwidth ranging from 5% to 100% wider than the bandwidth of the transponder signal.	Williams '419 discloses, explicitly and/or inherently, wherein the step of selecting and extracting a transponder signal comprises the step of: filtering a transponder signal with a band pass filter having a bandwidth ranging from 5% to 100% wider than the bandwidth of the transponder signal. *See* claim 14, *supra*. *See, e.g.*:

Asserted Claims	Williams '419
	Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 5:55–6:7: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM signals. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder

Asserted Claims	Williams '419
	signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
16. The method of claim 14 wherein the step of combining comprises frequency translating the selected and extracted transponder channels to a variable frequency before combining.	Williams '419 discloses, explicitly and/or inherently, wherein the step of combining comprises frequency translating the selected and extracted transponder channels to a variable frequency before combining. *See* claim 14, *supra*. *See, e.g.*: Williams '419 at 1:29–43: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units.

Asserted Claims	Williams '419
	Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program



Asserted Claims	Williams '419
	associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200

Asserted Claims	Williams '419
	MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such

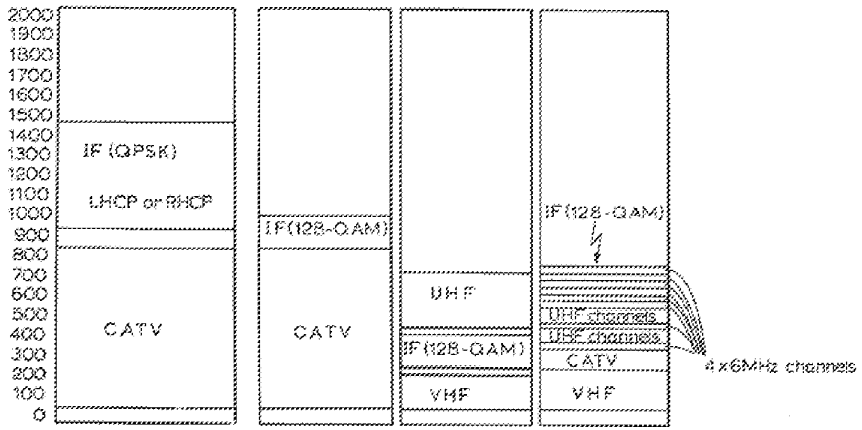
Asserted Claims	Williams '419
	groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard

Asserted Claims	Williams '419
	terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for

Asserted Claims	Williams '419
	elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 2:

Asserted Claims	Williams '419
	 FIG. 2 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
17. The method of claim 15 further comprising frequency translating the selected transponder channels to a predetermined frequency before combining.	Williams '419 discloses, explicitly and/or inherently, further comprising frequency translating the selected transponder channels to a predetermined frequency before combining. *See* claim 15, *supra*. *See, e.g.*:

Asserted Claims	Williams '419
	Williams '419 at 1:29–43: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals.



Asserted Claims	Williams '419
	Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including,

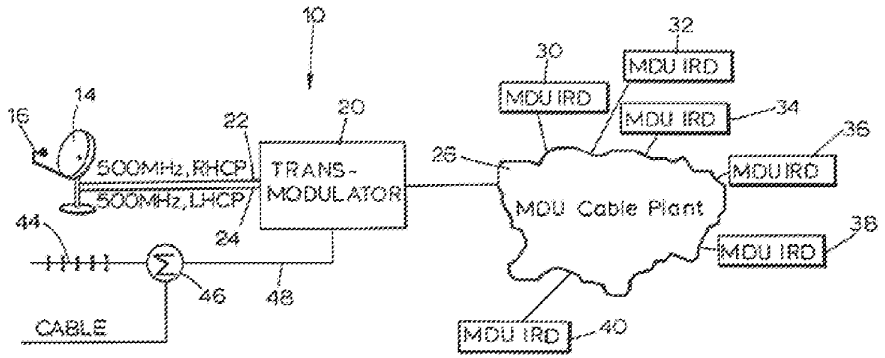
Asserted Claims	Williams '419
	for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals.

Asserted Claims	Williams '419
	The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same

Asserted Claims	Williams '419
	modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter

Asserted Claims	Williams '419
	66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte

Asserted Claims	Williams '419
	data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 2:  FIG. 2 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419



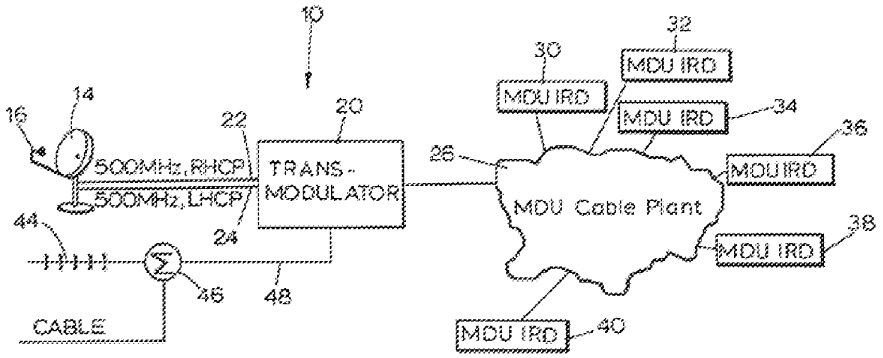
Asserted Claims	Williams '419
	with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
18. The method of claim 14 further comprising the step of splitting the composite signal inside a home and distributing to a plurality of IRDs.	Williams '419 discloses, explicitly and/or inherently, further comprising the step of splitting the composite signal inside a home and distributing to a plurality of IRDs. *See* claim 14, *supra*. *See, e.g.*: Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband

Asserted Claims	Williams '419
	signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The

Asserted Claims	Williams '419
	dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 4:48–54: Accordingly, apartment dwellers, for instance within a MDU system of this invention, can still use the dual mode IRD of the present invention if they move within a currently available SFH system, and conversely, single family home dwellers can still use the dual mode IRD of the present invention if they move within a MDU system of this invention. Williams '419 at 4:55–61: In a still further aspect of this invention, an MDU adapter enables a presently available IRD used within a current signal distribution system for SFHs (SFH IRD), to be compatible with a signal distribution system for MDUs of this invention. The MDU adapter demodulates a selected one of the received MDU network signals and modulates the selected signal in a manner compatible with the SFH IRD. Williams '419 at 7:1–8: Each of the IRDs 30-40 receives the 32, QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates at least a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated

Asserted Claims	Williams '419
	signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:28–33: After the control unit 72 identifies all of the empty or unused frequency bands, this information is preferably stored in non-volatile memory. Operator selection (e.g., by means of a keypad) may also be utilized to select or de-select frequency bands, either alone or in conjunction with an automated system. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter

Asserted Claims	Williams '419
	66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at 15:54–62: The program multiplexed data is provided to a demultiplexer 120 which is also responsive to the controller (not shown). The demultiplexer 120, which may be any standard demultiplexer, extracts one of the five to eight A-V programs from the program multiplexed data signal and provides a data stream having data pertaining to the extracted



Asserted Claims	Williams '419
	program (as identified by the controller) to a decoder having an MPEG video decoder 122, an MPEG audio decoder 123 and a data processor 124. Williams '419 at Fig. 1:  FIG. 1 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
19. The method of claim 14 wherein the transponder request signal is transmitted over the cable from an IRD and all IRDs receive the same composite signal.	Williams '419 discloses, explicitly and/or inherently, wherein the transponder request signal is transmitted over the cable from an IRD and all IRDs receive the same composite signal. *See* claim 14, *supra*.

Asserted Claims	Williams '419
	See, e.g.: Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The MDU adapter demodulates a selected one of the received MDU network signals and modulates the selected signal in a manner compatible with the SFH IRD. Williams '419 at 6:8–27:

Asserted Claims	Williams '419
	The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:1–8: Each of the IRDs 30-40 receives the 32, QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates at least a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. Williams '419 at 8:31–41: The L-band RHCP and LHCP signals (16 each) are linked to a set of up to 32 transmodulator channels, each of which includes a tuner 54, a satellite decoder 56, a packetizer 58, a cable encoder 60, and an upconverter 62. Each transmodulator channel decodes and transmodulates one of the 32 transponder signals associated with the downlink signal in essentially the same manner and, as a result, the operation of only one

Asserted Claims	Williams '419
	of the 32 transmodulator channels will be described herein. It should be understood that a greater or lesser number of transmodulator channels may alternatively be provided. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:56–67: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. The control unit 72 may control, for example, tuning parameters, such as the output frequencies of the tuners 54 and may select the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of

Asserted Claims	Williams '419
	interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 1:  FIG. 1 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419

Asserted Claims	Williams '419
	with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
20. The method of claim 14 wherein the transponder request signal is transmitted over a wireless link to the ODU.	Williams '419 discloses, explicitly and/or inherently, wherein the transponder request signal is transmitted over a wireless link to the ODU. *See* claim 14, *supra*. *See, e.g.*: Williams '419 at 1:17–28: Audio/visual/data (A-V) signal distribution systems generally rely on either a cable network or on free-space propagation for delivering A-V signals, such as television signals, to individual users or subscribers. Cable-based A-V signal distribution systems transmit one or more individual A-V signals or "channels" over wire, while free-space propagation systems transmit one or more channels over-the-air, i.e., in a wireless manner. Most large-scale cable and wireless signal distribution systems broadcast a broadband A-V signal having a plurality of individual A-V signals modulated onto one or more carrier frequencies within a discernable frequency band. Williams '419 at 1:29–43: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to

Asserted Claims	Williams '419
	different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 2:41–55: Furthermore, the receiving antennas or dishes associated with land-based or satellite-based wireless signal distribution systems are typically large and cumbersome. For example, C-band satellite dishes are generally in the range of four to five feet in diameter and, therefore, require a large amount of operating space. As a result, it can be difficult, if not practically impossible, to install a receiving antenna for each individual unit within a multiple dwelling unit (MDU), such as an apartment, condominium or townhome complex. Reception of a particular satellite signal is made even more difficult in MDUs when, as is generally the case, some of the individual dwelling units therein do not have any walls or outside exposure facing the direction in which the receiving antenna must be pointed, or these dwelling units are shadowed by surrounding buildings or other obstructions. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 3:48–65:

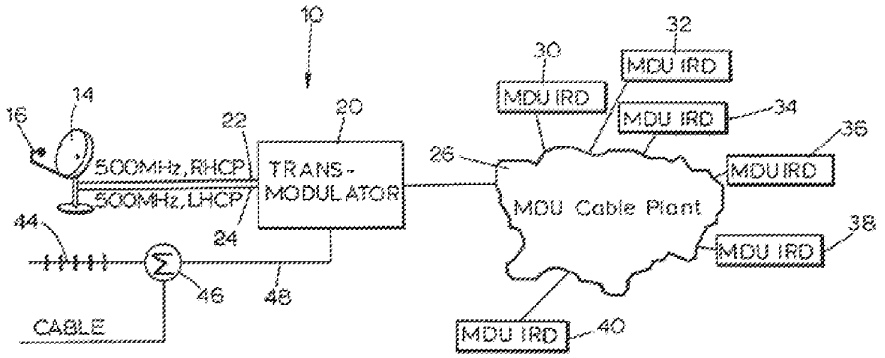
Asserted Claims	Williams '419
	According to another aspect of the present invention, a signal distribution system that distributes first and second signals over a communication channel to a plurality of individual receivers includes a main receiver and a second receiver disposed at a local site for receiving the first and second signals, respectively. A transmodulator coupled to the main receiver transmodulates the first signal from a first modulation scheme, such as a QPSK modulation scheme, to a second modulation scheme, such as a 128-QAM modulation scheme, to produce a transmodulated third signal. A signal combiner coupled to the second receiver and to the transmodulator combines the transmodulated third signal at a first set of carrier frequency bands and the second signal at a second set of carrier frequency bands to produce a combined signal. A transmitter then transmits the combined signal over a cable or a wireless network in a manner capable of being received at the plurality of individual receivers. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 5:25–40:

Asserted Claims	Williams '419
	By the way of example only, the signal distribution system of the present invention is described herein as redistributing a broadband Ku-band satellite signal (comprising up to 32, QPSK-modulated transponder signals transmitted from one or more satellites at a carrier frequency band centered around approximately 12.45 GHz) to receiver units within an MDU. It is understood however, that the signal distribution system of the present invention can be used to redistribute any other type of satellite or land-based wireless signal. The term program multiplex (PM) signal is used herein to describe any single or multiplex of purely visual (such as video), purely audio, or purely data signals as well as a signal comprising any combination of audio, visual, data or other signals including, for example, television signals, digital data signals, etc. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 6:52–67: Preferably, the transmodulator 20 transmodulates the two 500 MHz-wide QPSK-modulated downlink signals into a 128-QAM-modulated signal having 32, 6 MHz-wide

Asserted Claims	Williams '419
	channels, wherein each of the 6 MHz-wide channels corresponds to one of the 32 original transponder signals. The transmodulator 20 may then place each of these 32, 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate the received satellite signals. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '419 at 7:1–8: Each of the IRDs 30-40 receives the 32, QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates at least a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
21[a] 21. The method of claim 14 further comprising the steps of: frequency translating the selected transponder channels to a variable frequency before combining; and	Williams '419 discloses, explicitly and/or inherently, frequency translating the selected transponder channels to a variable frequency before combining. *See* claims 14, 16, *supra*. *See, e.g.*:

Page 1552 of 4862

Asserted Claims	Williams '419
	Williams '419 at 1:29–43: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals.



Asserted Claims	Williams '419
	Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including,

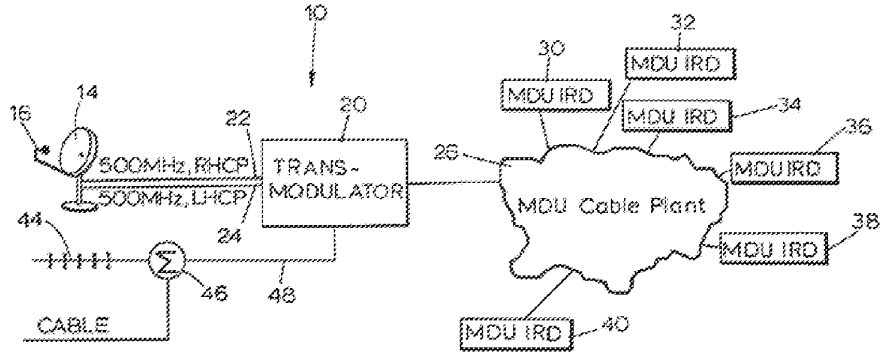
Asserted Claims	Williams '419
	for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals.

Asserted Claims	Williams '419
	The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same

Asserted Claims	Williams '419
	modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter

Asserted Claims	Williams '419
	66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte

Asserted Claims	Williams '419
	data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 1:  FIG. 1 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.



Asserted Claims	Williams '419
21[b] splitting the composite signal inside a home and distributing to a plurality of IRDs.	Williams '419 discloses, explicitly and/or inherently, splitting the composite signal inside a home and distributing to a plurality of IRDs. *See* claims 14, 18, *supra*. *See, e.g.*: Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is

Asserted Claims	Williams '419
	smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated

Asserted Claims	Williams '419
	signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 4:48–54: Accordingly, apartment dwellers, for instance within a MDU system of this invention, can still use the dual mode IRD of the present invention if they move within a currently available SFH system, and conversely, single family home dwellers can still use the dual mode IRD of the present invention if they move within a MDU system of this invention. Williams '419 at 4:55–61: In a still further aspect of this invention, an MDU adapter enables a presently available IRD used within a current signal distribution system for SFHs (SFH IRD), to be compatible with a signal distribution system for MDUs of this invention. The MDU adapter demodulates a selected one of the received MDU network signals and modulates the selected signal in a manner compatible with the SFH IRD. Williams '419 at 7:1–8: Each of the IRDs 30-40 receives the 32, QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates at least a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a

Asserted Claims	Williams '419
	signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:28–33: After the control unit 72 identifies all of the empty or unused frequency bands, this information is preferably stored in non-volatile memory. Operator selection (e.g., by means of a keypad) may also be utilized to select or de-select frequency bands, either alone or in conjunction with an automated system. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 14:27–54:

Asserted Claims	Williams '419
	The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at 15:54–62: The program multiplexed data is provided to a demultiplexer 120 which is also responsive to the controller (not shown). The demultiplexer 120, which may be any standard demultiplexer, extracts one of the five to eight A-V programs from the program multiplexed data signal and provides a data stream having data pertaining to the extracted program (as identified by the controller) to a decoder having an MPEG video decoder 122, an MPEG audio decoder 123 and a data processor 124. Williams '419 at Fig. 1:

Asserted Claims	Williams '419
	 FIG. 1 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
22. The method of claim 21 wherein the transponder request signal is transmitted over the cable from an IRD.	Williams '419 discloses, explicitly and/or inherently, wherein the transponder request signal is transmitted over the cable from an IRD. *See* claims 19, 21, *supra*. *See, e.g.*: Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna

Asserted Claims	Williams '419
	that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal

Asserted Claims	Williams '419
	distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 4:48–54: Accordingly, apartment dwellers, for instance within a MDU system of this invention, can still use the dual mode IRD of the present invention if they move within a currently available SFH system, and conversely, single family home dwellers can still use the dual mode IRD of the present invention if they move within a MDU system of this invention. Williams '419 at 4:55–61: In a still further aspect of this invention, an MDU adapter enables a presently available IRD used within a current signal distribution system for SFHs (SFH IRD), to be compatible with a signal distribution system for MDUs of this invention. The MDU adapter demodulates a selected one of the received MDU network signals and modulates the selected signal in a manner compatible with the SFH IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a

Asserted Claims	Williams '419
	number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:1–8: Each of the IRDs 30-40 receives the 32, QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates at least a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. Williams '419 at 8:31–41: The L-band RHCP and LHCP signals (16 each) are linked to a set of up to 32 transmodulator channels, each of which includes a tuner 54, a satellite decoder 56, a packetizer 58, a cable encoder 60, and an upconverter 62. Each transmodulator channel decodes and transmodulates one of the 32 transponder signals associated with the downlink signal in essentially the same manner and, as a result, the operation of only one of the 32 transmodulator channels will be described herein. It should be understood that a greater or lesser number of transmodulator channels may alternatively be provided. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder

Asserted Claims	Williams '419
	signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:56–67: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. The control unit 72 may control, for example, tuning parameters, such as the output frequencies of the tuners 54 and may select the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error

Asserted Claims	Williams '419
	during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
23. The method of claim 21 wherein the transponder request signal is transmitted over a wireless link to the ODU.	Williams '419 discloses, explicitly and/or inherently, wherein the transponder request signal is transmitted over a wireless link to the ODU. *See* claims 20, 21, *supra*. *See, e.g.*: Williams '419 at 1:17–28: Audio/visual/data (A-V) signal distribution systems generally rely on either a cable network or on free-space propagation for delivering A-V signals, such as television signals, to individual users or subscribers. Cable-based A-V signal distribution systems transmit one or more individual A-V signals or "channels" over wire, while free-space propagation systems transmit one or more channels over-the-air, i.e., in a wireless manner. Most large-scale cable and wireless signal distribution systems broadcast a broadband A-V signal having a plurality of individual A-V signals modulated onto one or more carrier frequencies within a discernable frequency band. Williams '419 at 1:29–43:

Asserted Claims	Williams '419
	Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 2:41–55: Furthermore, the receiving antennas or dishes associated with land-based or satellite-based wireless signal distribution systems are typically large and cumbersome. For example, C-band satellite dishes are generally in the range of four to five feet in diameter and, therefore, require a large amount of operating space. As a result, it can be difficult, if not practically impossible, to install a receiving antenna for each individual unit within a multiple dwelling unit (MDU), such as an apartment, condominium or townhome complex. Reception of a particular satellite signal is made even more difficult in MDUs when, as is generally the case, some of the individual dwelling units therein do not have any walls or outside exposure facing the direction in which the receiving antenna must be pointed, or these dwelling units are shadowed by surrounding buildings or other obstructions. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is

Asserted Claims	Williams '419
	smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 3:48–65: According to another aspect of the present invention, a signal distribution system that distributes first and second signals over a communication channel to a plurality of individual receivers includes a main receiver and a second receiver disposed at a local site for receiving the first and second signals, respectively. A transmodulator coupled to the main receiver transmodulates the first signal from a first modulation scheme, such as a QPSK modulation scheme, to a second modulation scheme, such as a 128-QAM modulation scheme, to produce a transmodulated third signal. A signal combiner coupled to the second receiver and to the transmodulator combines the transmodulated third signal at a first set of carrier frequency bands and the second signal at a second set of carrier frequency bands to produce a combined signal. A transmitter then transmits the combined signal over a cable or a wireless network in a manner capable of being received at the plurality of individual receivers. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the

Asserted Claims	Williams '419
	first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 5:25–40: By the way of example only, the signal distribution system of the present invention is described herein as redistributing a broadband Ku-band satellite signal (comprising up to 32, QPSK-modulated transponder signals transmitted from one or more satellites at a carrier frequency band centered around approximately 12.45 GHz) to receiver units within an MDU. It is understood however, that the signal distribution system of the present invention can be used to redistribute any other type of satellite or land-based wireless signal. The term program multiplex (PM) signal is used herein to describe any single or multiplex of purely visual (such as video), purely audio, or purely data signals as well as a signal comprising any combination of audio, visual, data or other signals including, for example, television signals, digital data signals, etc. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local

Asserted Claims	Williams '419
	sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 6:52–67: Preferably, the transmodulator 20 transmodulates the two 500 MHz-wide QPSK-modulated downlink signals into a 128-QAM-modulated signal having 32, 6 MHz-wide channels, wherein each of the 6 MHz-wide channels corresponds to one of the 32 original transponder signals. The transmodulator 20 may then place each of these 32, 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate the received satellite signals. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '419 at 7:1–8: Each of the IRDs 30-40 receives the 32, QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates at least a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.

Asserted Claims	Williams '419
34. The method of claim 14, wherein selecting and extracting comprises applying a pass band filter transfer function to the digitized broadband signal.	Williams '419 discloses, explicitly and/or inherently, wherein selecting and extracting comprises applying a pass band filter transfer function to the digitized broadband signal. *See* claims 14, 15, *supra*. *See, e.g.*: Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 5:55–6:7: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM signals. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a

Asserted Claims	Williams '419
	transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
35. The method of claim 14, further comprising converting the selected signal to an analog signal using a digital to analog converter prior to combining.	Williams '419 discloses, explicitly and/or inherently, further comprising converting the selected signal to an analog signal using a digital to analog converter prior to combining. *See* claim 14, *supra*. *See, e.g.*: Williams '419 at 9:56–67: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. The

Page 1576 of 4862

Asserted Claims	Williams '419
	control unit 72 may control, for example, tuning parameters, such as the output frequencies of the tuners 54 and may select the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. Williams '419 at 15:63–16:20: The MPEG video decoder 122, which may be any standard MPEG2 video decoder commonly known in the art, operates to produce a digital video signal from the received bit stream and provides this digital signal to an NTSC encoder 125. The NTSC encoder 125, which may be any standard encoder, converts the received digital signal into an analog NTSC video signal and provides this signal to a television set 126 for display on the television screen, as is commonly known in the art. The MPEG audio decoder 123, which may be any standard audio decoder commonly known in the art, produces a digital audio signal from the received bit stream, and provides this audio bit stream to a D/A converter 127 which, in turn, provides an audio signal to the television set 126 for use in conjunction with the video signal developed by the NTSC encoder 125. The data processor 124 performs independent data processing or data functions on data within the decoded signal. The data processor 124 may, for example, decode, display and/or run web pages, software programs, etc. delivered via the satellite communication channel. In addition or in the alternative, other video, audio and/or data signals may be processed or output in known manners. Likewise, terrestrial signals may be diplexed off of the cable network 26 and provided to a tuner associated with a user television, VCR, etc. for demodulation in manners known in the art. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.

Asserted Claims	Williams '419
36. The method of claim 14, wherein the combining is performed in the digital domain.	Williams '419 discloses, explicitly and/or inherently, wherein the combining is performed in the digital domain. *See* claim 14, *supra*. *See, e.g.*: Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is

Asserted Claims	Williams '419
	smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated

Asserted Claims	Williams '419
	signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 4:48–54: Accordingly, apartment dwellers, for instance within a MDU system of this invention, can still use the dual mode IRD of the present invention if they move within a currently available SFH system, and conversely, single family home dwellers can still use the dual mode IRD of the present invention if they move within a MDU system of this invention. Williams '419 at 4:55–61: In a still further aspect of this invention, an MDU adapter enables a presently available IRD used within a current signal distribution system for SFHs (SFH IRD), to be compatible with a signal distribution system for MDUs of this invention. The MDU adapter demodulates a selected one of the received MDU network signals and modulates the selected signal in a manner compatible with the SFH IRD. Williams '419 at 5:25–40: By the way of example only, the signal distribution system of the present invention is described herein as redistributing a broadband Ku-band satellite signal (comprising up to 32, QPSK-modulated transponder signals transmitted from one or more satellites at a carrier frequency band centered around approximately 12.45 GHz) to receiver units within an MDU. It is understood however, that the signal distribution system of the present invention can be used to redistribute any other type of satellite or land-based wireless signal. The term program multiplex (PM) signal is used herein to describe any single or multiplex of purely visual (such as video), purely audio, or purely data signals as well as a signal comprising any combination of audio, visual, data or other signals including, for example, television signals, digital data signals, etc.

Asserted Claims	Williams '419
	Williams '419 at 7:9–36: Referring now to FIG. 2, representative methods of combining the transmodulated transponder signals along with terrestrial signals on the cable network 26 are illustrated. The left-most column of FIG. 2 illustrates a previously known method of placing QPSK-modulated signals along with terrestrial signals on a cable network. According to this scheme, all existing terrestrial signals (including cable TV signals) are distributed at, for example, VHF and UHF carrier frequencies below 950 MHz while one of the 500 MHz-wide QPSK-modulated signals (associated with either the LHCP or the RHCP component of the satellite signal) is placed directly on the cable network at the unused band between about 950 MHz and 1450 MHz. A major problem with this configuration is that only the RHCP or the LHCP transponder signals can be placed on a standard cable network at any given time which, in turn, prevents IRDs within an MDU from decoding or receiving channels associated with the other of the LHCP or the RHCP transponder signals. While this problem can be overcome by running two cable lines throughout an MDU or by utilizing a high frequency cable plant capable of approximately 2 GHz or greater bandwidth, these solutions require additional equipment and expense and are not adaptable to most existing cable plants now in use. Furthermore, the signals provided at the 950 MHz to 1450 MHz band can be severely degraded by the cable plant due to the poor high frequency propagation properties of many existing cable plants, especially older cable plants. Williams '419 at 7:37–46: The three right-most columns of FIG. 2 illustrate methods of combining the 32, 6 MHz-wide, 128-QAM-modulated signals with existing terrestrial signals on the cable network 26. The second left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals in sequence at a band between about 806 MHz and 998 MHz directly above the common CATV channels. This configuration can be used with higher grade cable networks that propagate signals at up to 1000 MHz without significant degradation.

Asserted Claims	Williams '419
	Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
37. The method of claim 17, wherein frequency translating comprises using a digital mixer to apply a rotating phasor to the data samples to translate their frequency.	Williams '419 discloses, explicitly and/or inherently, wherein frequency translating comprises using a digital mixer to apply a rotating phasor to the data samples to translate their frequency. *See* claim 17, *supra*. *See, e.g.*: Williams '419 at 1:29–43:

Asserted Claims	Williams '419
	Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between

Asserted Claims	Williams '419
	about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the

Asserted Claims	Williams '419
	transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate

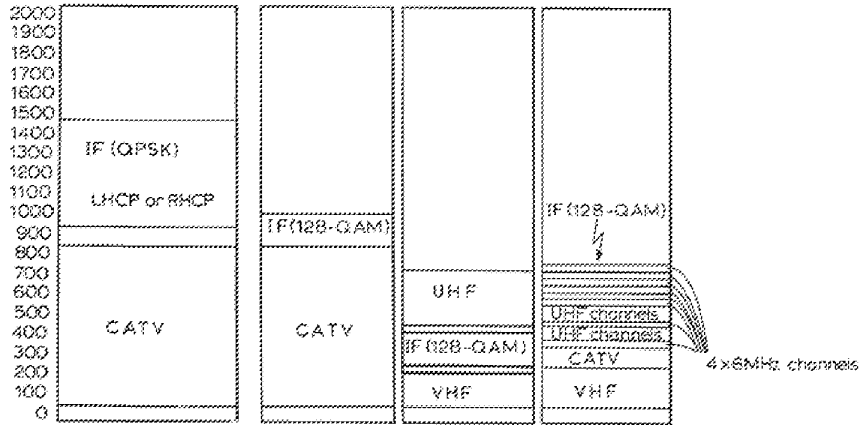
Asserted Claims	Williams '419
	frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals.

Asserted Claims	Williams '419
	Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62:

Asserted Claims	Williams '419
	If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error

Asserted Claims	Williams '419
	during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
38. The method of claim 14, further comprising frequency translating the digitized broadband signal prior to selecting and extracting transponder signal.	Williams '419 discloses, explicitly and/or inherently, further comprising frequency translating the digitized broadband signal prior to selecting and extracting transponder signal. *See* claims 14, *supra*. *See, e.g.*: Williams '419 at 1:29–43: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units.

Asserted Claims	Williams '419
	Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program



Asserted Claims	Williams '419
	associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200

Asserted Claims	Williams '419
	MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such

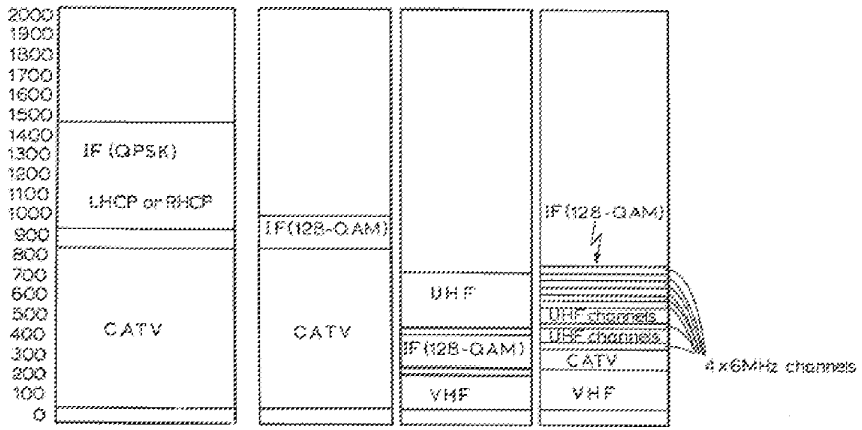
Asserted Claims	Williams '419
	groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard

Asserted Claims	Williams '419
	terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for

Asserted Claims	Williams '419
	elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 2:

Asserted Claims	Williams '419
	 FIG. 2 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
39. The method of claim 38, wherein frequency translating comprises translating the original digitized broadband signal to locate a selected transponder channel at baseband.	Williams '419 discloses, explicitly and/or inherently, wherein frequency translating comprises translating the original digitized broadband signal to locate a selected transponder channel at baseband. *See* claim 38, *supra*. *See, e.g.*:

Asserted Claims	Williams '419
	Williams '419 at 1:29–43: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals.



Asserted Claims	Williams '419
	Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including,

Asserted Claims	Williams '419
	for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals.

Asserted Claims	Williams '419
	The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same

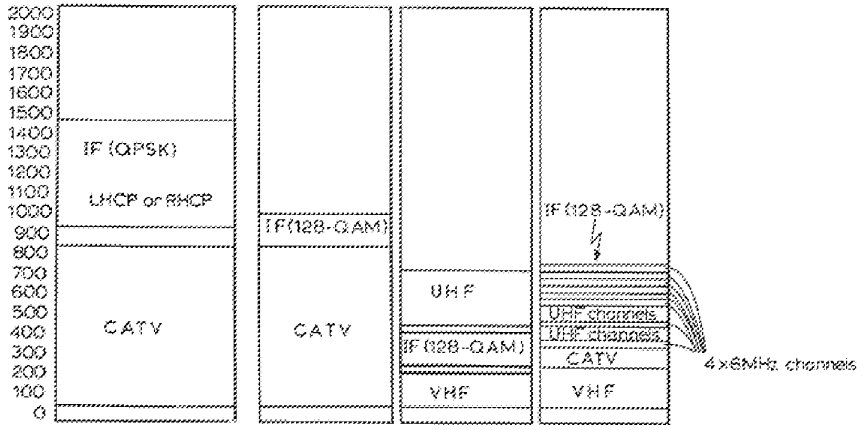
Asserted Claims	Williams '419
	modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter

Asserted Claims	Williams '419
	66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte

Asserted Claims	Williams '419
	data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 2:  FIG. 2 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419

Asserted Claims	Williams '419
	with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
40. The method of claim 14, further comprising maintaining a channel translation table at the outdoor unit, the channel translation table specifying assigned frequency slots for transponder channels in the composite signal.	Williams '419 discloses, explicitly and/or inherently, further comprising maintaining a channel translation table at the outdoor unit, the channel translation table specifying assigned frequency slots for transponder channels in the composite signal. *See* claim 14, *supra*. *See, e.g.*: Williams '419 at 1:29–43: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets

Asserted Claims	Williams '419
	associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD.



Asserted Claims	Williams '419
	Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50:

Asserted Claims	Williams '419
	The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial

Asserted Claims	Williams '419
	signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector

Asserted Claims	Williams '419
	does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54:

Asserted Claims	Williams '419
	The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 2:

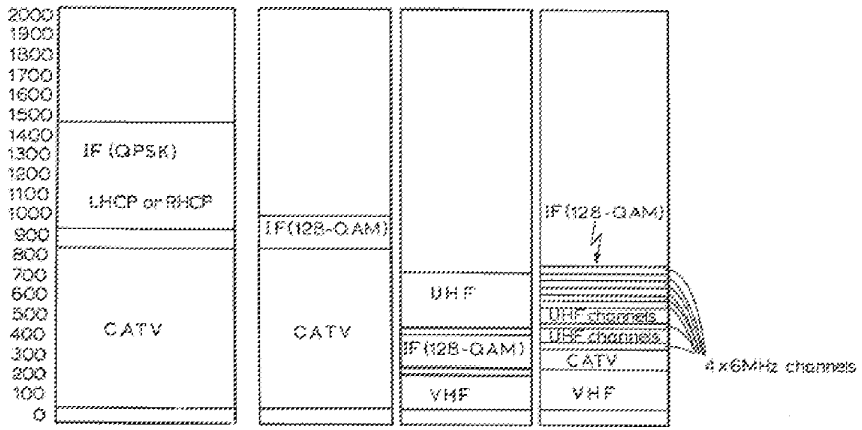
	 FIG. 2 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
41. The method of claim 38, further comprising providing the channel translation table to the IRD to allow the IRD to tune to a desired selected translated transponder channel.	Williams '419 discloses, explicitly and/or inherently, further comprising providing the channel translation table to the IRD to allow the IRD to tune to a desired selected translated transponder channel. *See* claim 38, *supra*. *See, e.g.*:

Asserted Claims	Williams '419
	Williams '419 at 1:29–43: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals.



Asserted Claims	Williams '419
	Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including,

Asserted Claims	Williams '419
	for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals.

Asserted Claims	Williams '419
	The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same

Asserted Claims	Williams '419
	modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter

Asserted Claims	Williams '419
	66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte

Asserted Claims	Williams '419
	data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 2:  FIG. 2 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419

Asserted Claims	Williams '419
	with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
42. The method of claim 14, wherein selecting and extracting comprises low-pass filtering the translated digitized broadband signal thereby substantially removing signal information from non-selected transponder channels.	Williams '419 discloses, explicitly and/or inherently, wherein selecting and extracting comprises low-pass filtering the translated digitized broadband signal thereby substantially removing signal information from non-selected transponder channels. *See* claim 14, *supra*. *See, e.g.*: Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 5:55–6:7: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM signals. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down

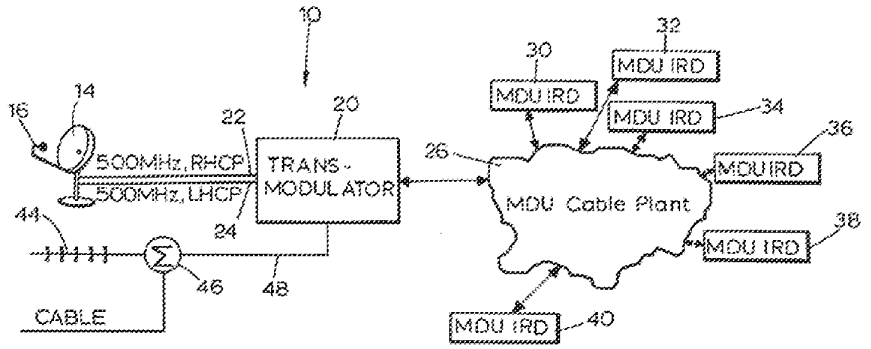
Asserted Claims	Williams '419
	to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.

INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,130,576 in view of Williams '873

U.S. Patent No. 6,493,873 ("Williams '873") was filed on January 20, 1998 and issued on December 10, 2002. Williams '873 therefore qualifies as prior art to the '576 patent under, at least, (pre-AIA) 35 U.S.C. § 102(a) and/or (e). For the reasons listed below, Williams '873 invalidates the asserted claims of the '576 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix A, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Williams '873
14[pre] 14. A method of communicating a plurality of transponder signals from a satellite outdoor unit (ODU) that receives a plurality of satellite broadband signals to an integrated receiver decoder (IRD) over a single cable connected to the ODU, the method comprising the steps of:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Williams '873 discloses, explicitly and/or inherently, a method of communicating a plurality of transponder signals from a satellite outdoor unit (ODU) that receives a plurality of satellite broadband signals to an integrated receiver decoder (IRD) over a single cable connected to the ODU. *See, e.g.*:

[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '576 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.



Asserted Claims	Williams '873
	Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 2:15–25: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '873 at 2:26–44: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g., between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder

Asserted Claims	Williams '873
	signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '873 at 2:45–59: Furthermore, the receiving antennas or dishes associated with land-based or satellite-based wireless signal distribution systems are typically large and cumbersome. For example, C-band satellite dishes are generally in the range of four to five feet in diameter and, therefore, require a large amount of operating space. As a result, it can be difficult, if not practically impossible, to install a receiving antenna for each individual unit within a multiple dwelling unit (MDU), such as an apartment, condominium or townhome complex. Reception of a particular satellite signal is made even more difficult in MDUs when, as is generally the case, some of the individual dwelling units therein do not have any walls or outside exposure facing the direction in which the receiving antenna must be pointed, or these dwelling units are shadowed by surrounding buildings or other obstructions. Williams '873 at 3:13–32: One system proposed by the European Telecommunications Standards Institute (ETSI) in the area of Satellite Master Antenna Television (SMATV) receives a QPSK modulated satellite television signal (which may be combined with terrestrial TV signals) and remodulates this signal according to a 64 quadrature amplitude modulation (64-QAM) technique. The SMATV system then sends this remodulated signal out over cable to one or more adjacent buildings. Likewise, U.S. Pat. No. 5,173,775 discloses a system that remodulates data portions of a satellite television signal from one modulation scheme to another, such as from FM to AM, for retransmission to subscribers. However, these systems do not specifically demonstrate how to propagate remodulated satellite signals and existing cable or terrestrial signals on the same cable line or other transmission channel in an efficient manner or demonstrate how to remodulate and broadcast a large number of

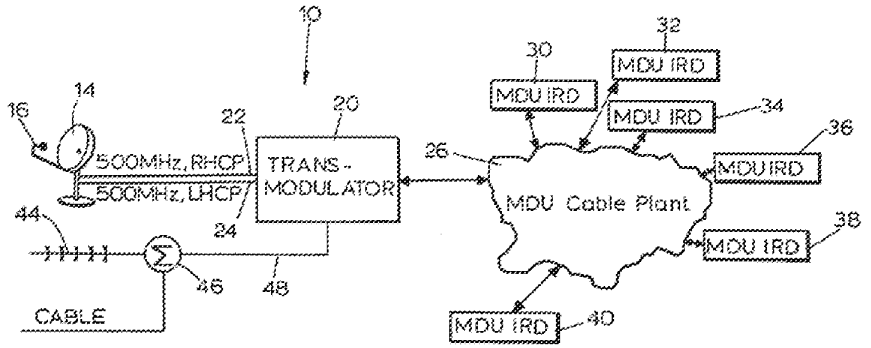
Asserted Claims	Williams '873
	transponder signals associated with one or more satellites over the same cable line or other transmission channel to one or more adjacent buildings. Williams '873 at 3:33–47: The above-identified parent application discloses a signal redistribution system that transmodulates each of, for example, 32 received satellite transponder signals into a different modulation scheme and transmits each of these transmodulated signals, along with standard terrestrial signals, to each of a set of receivers within an MDU. The transmodulator disclosed in this application includes a separate channel having a satellite signal demodulator coupled to a signal remodulator for each of the received satellite transponder signals. As a result, this transmodulator unit tends to be expensive, especially when used in an MDU which includes fewer satellite signal receivers or subscribers than there are channels in the transmodulator unit, i.e., in MDUs that will never need all of the channels provided by the transmodulator unit. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which

Asserted Claims	Williams '873
	uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 5:59–6:11: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 6:12–34: The transmodulator 20 remodulates or transmodulates a subset of the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to any lower bandwidth. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes and/or by remodulating less than all of the received transponder signals associated with the composite signal. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal having less than all of the received transponder signals on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute

Asserted Claims	Williams '873
	the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the

Asserted Claims	Williams '873
	transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at Fig. 1:  FIG. 1 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.

Asserted Claims	Williams '873
14[a] communicating a transponder request signal to the ODU from the IRD;	Williams '873 discloses, explicitly and/or inherently, communicating a transponder request signal to the ODU from the IRD. *See, e.g.*: Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the



Asserted Claims	Williams '873
	individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 4:39–44: Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 4:45–59: The signal distribution system may include a second receiver adapted to receive a terrestrial signal while the combiner may combine the multiplicity of transmodulated signals with the terrestrial signal to produce the combined signal. Furthermore, a reception device coupled to the communication channel at one of the individual receivers may include a receiver that receives the combined signal, a demodulator that demodulates a portion of the received combined signal and an individual transmitter that transmits one of the request signals to the transmodulator indicating one of the plurality of program multiplex signals to be transmodulated. If desired, the transmodulator channels may transmodulate between a quadrature phase shift keying (QPSK) modulation scheme and a quadrature amplitude modulation (QAM) scheme, such as a 128-QAM scheme. Williams '873 at 4:60–5:5: According to a still further aspect of the present invention, a method of distributing a subset of a plurality of individual signals associated with a composite signal to multiple individual receivers includes the steps of receiving the composite signal, receiving a request signal from each of the individual receivers and choosing the subset of the plurality of the individual signals to be distributed based on the received request signals. Each of the

Asserted Claims	Williams '873
	subset of the plurality of the individual signals is transmodulated from a first modulation scheme to a second modulation scheme and is transmitted over a communication channel to the individual receivers. Williams '873 at 6:35–46: In order to determine which of the received satellite transponder signals should be transmodulated at any particular time, the transmodulator 20 receives and decodes requests for particular channels or satellite signals from each of the IRDs 30-40 that are active, determines from these requests which of the set of satellite or transponder signals to transmodulate and then tunes to and transmodulates only those selected satellite or transponder signals. The transmodulator sends the updated frequency index to the receiver via side data. If no transponders are available to fulfill the request, the transmodulator sends an error message to the receiver indicating that no transponder is available. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol

Asserted Claims	Williams '873
	typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 9:7–27: The L-band RHCP and LHCP signals are each linked to a series of switches 53 associated with a set of transmodulator channels of the transmodulator 20. Preferably, the number of transmodulator channels within the transmodulator 20 is chosen in conjunction with the number of receiver units or IRDs connected to the transmodulator 20. Typically, the fewer number of IRDs, the fewer number of transmodulator channels that are necessary. Generally speaking, however, the transmodulator 20 will not require more channels than the number of IRDs being supported and, in fact, will typically require less channels because it is not likely that all of the simultaneously operating IRDs being supported by the transmodulator 20 will be tuned to different transponder signals at the same time. If desired, the number of transponder channels may be chosen using any desired statistical analysis, taking into account, for example, the number of supported IRDs, the likelihood that the IRDs will be used at the same time, the likelihood that different IRDs will be tuned to the same satellite transponder signal, etc. Of course, the transmodulator 20 may be designed to be easily upgraded to add more transmodulator channels if necessary. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches

Asserted Claims	Williams '873
	53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator channels to tune to a specific one of the selected transponder signals. The control unit 72 may assign the transmodulator channels to tune to different transponder signals on a first come, first serve basis, by determining which of the transponder signals have the highest number of active requests associated therewith or using any other desired technique. Williams '873 at 11:22–35: If desired, the control unit 72 may provide a signal via side data to each of the IRDs 30-40 specifying which transponder signals are being transmodulated and transmitted over the cable network 26 and the frequencies at which the transmodulated transponder signals are located on the cable network 26. Also, if desired, when the control unit 72 receives

Asserted Claims	Williams '873
	requests for more transponder signals than there are transmodulator channels, the control unit 72 may send a signal to one or more of the IRDs 30-40 indicating that the requested signal cannot be decoded at, the present time because all of the transmodulator channels are being used to transmodulate other transponder signals. This communication may be performed using the cable network 26 or using any other wire or wireless network. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at Fig. 1:

Asserted Claims	Williams '873
	 FIG. 1 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
14[b] in the ODU, digitizing the plurality of satellite broadband signals, selecting and extracting a plurality of transponder signals from the received satellite broadband signals, wherein the selecting is responsive to the transponder request signals;	Williams '873 discloses, explicitly and/or inherently, in the ODU, digitizing the plurality of satellite broadband signals, selecting and extracting a plurality of transponder signals from the received satellite broadband signals, wherein the selecting is responsive to the transponder request signals. *See, e.g.*: Williams '873 at Abstract:

Asserted Claims	Williams '873
	A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 4:4–15:

Asserted Claims	Williams '873
	According to another aspect of the present invention, a signal distribution system adapted to receive a composite signal having a multiplicity of transponder signals therein includes a transmodulator that transmodulates a selected one of the transponder signals from a first modulation scheme to a second modulation scheme to produce a transmodulated signal and a transmitter that transmits the transmodulated signal over a communication channel to a plurality of individual receivers. A receiver receives a request signal from each of the plurality of individual receivers and a controller selects the selected transponder signal in response to the request signals. Williams '873 at 4:39–44: Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 6:35–46: In order to determine which of the received satellite transponder signals should be transmodulated at any particular time, the transmodulator 20 receives and decodes requests for particular channels or satellite signals from each of the IRDs 30-40 that are active, determines from these requests which of the set of satellite or transponder signals to transmodulate and then tunes to and transmodulates only those selected satellite or transponder signals. The transmodulator sends the updated frequency index to the receiver via side data. If no transponders are available to fulfill the request, the transmodulator sends an error message to the receiver indicating that no transponder is available. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable

Asserted Claims	Williams '873
	network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 9:40–48:

Asserted Claims	Williams '873
	The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator channels to tune to a specific one of the selected transponder signals. The control unit 72 may assign the transmodulator channels to tune to different transponder signals on a first come, first serve basis, by determining which of the transponder signals have the highest number of active requests associated therewith or using any other desired technique. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher

Asserted Claims	Williams '873
	bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:1–6: After the control unit 72 identifies all of the empty or unused frequency bands, this information is preferably stored in non-volatile memory. Operator selection (e.g., by means of a keypad) may also be utilized to select or de-select frequency bands, either alone or in conjunction with an automated system. To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
14[c] combining extracted selected transponder signals into a composite signal;	Williams '873 discloses, explicitly and/or inherently, combining extracted selected transponder signals into a composite signal. *See, e.g.*:

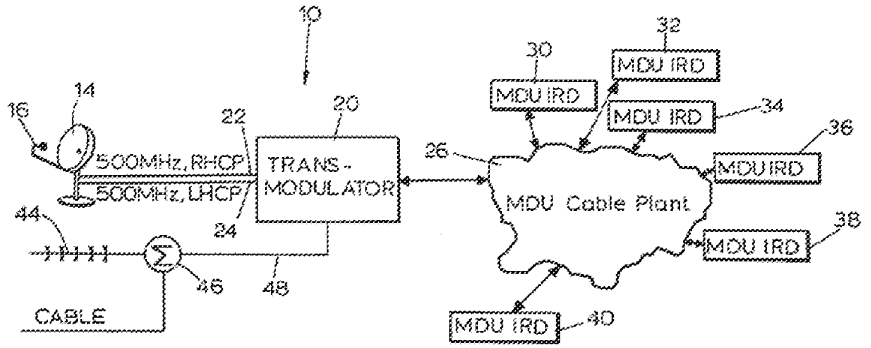
Asserted Claims	Williams '873
	Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which uses these requests to select Which of the portions of the broadband signal will be transmodulated.

Asserted Claims	Williams '873
	Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 4:39–44: Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 4:45–59: The signal distribution system may include a second receiver adapted to receive a terrestrial signal while the combiner may combine the multiplicity of transmodulated signals with the terrestrial signal to produce the combined signal. Furthermore, a reception device coupled to the communication channel at one of the individual receivers may include a receiver that receives the combined signal, a demodulator that demodulates a

Asserted Claims	Williams '873
	portion of the received combined signal and an individual transmitter that transmits one of the request signals to the transmodulator indicating one of the plurality of program multiplex signals to be transmodulated. If desired, the transmodulator channels may transmodulate between a quadrature phase shift keying (QPSK) modulation scheme and a quadrature amplitude modulation (QAM) scheme, such as a 128-QAM scheme. Williams '873 at 5:30–44: By the way of example only, the signal distribution system of the present invention is described herein as redistributing a broadband Ku-band satellite signal (comprising up to 32, QPSK-modulated transponder signals transmitted from one or more satellites at a carrier frequency band centered around approximately 12.45 GHz) to receiver units within an MDU. It is understood however, that the signal distribution system of the present invention can be used to redistribute any other type of satellite or land-based wireless signal. The term program multiplex (PM) signal is used herein to describe any single or multiplex of purely visual (such as video), purely audio, or purely data signals as well as a signal comprising any combination of audio, visual, data or other signals including, for example, television signals, digital data signals, etc. Williams '873 at 7:48–8:8: Referring now to FIG. 2, representative methods of combining the transmodulated transponder signals along with terrestrial signals on the cable network 26 are illustrated. The left-most column of FIG. 2 illustrates a previously known method of placing QPSK-modulated signals along with terrestrial signals on a cable network. According to this scheme, all existing terrestrial signals (including cable TV signals) are distributed at, for example, VHF and UHF carrier frequencies below 950 MHz while one of the 500 MHz-wide QPSK-modulated signals (associated with either the LHCP or the RHCP component of the satellite signal) is placed directly on the cable network at the unused band between about 950 MHz and 1450 MHz. A major problem with this configuration is that only the RHCP or the LHCP transponder signals can be placed on a 1450 MHz capable cable network at any given time which, in turn, prevents IRDs within an MDU from decoding or

Asserted Claims	Williams '873
	receiving channels associated with the other of the LHCP or the RHCP transponder signals. While this problem can be overcome by running two cable lines throughout an MDU or by utilizing a high frequency cable plant capable of approximately 2 GHz or greater bandwidth, these solutions require additional equipment and expense and are not adaptable to most existing cable plants now in use. Furthermore, the signals provided at the 950 MHz to 1450 MHz band can be severely degraded by the cable plant due to the poor high frequency propagation properties of many existing cable plants, especially older cable plants. Williams '873 at 8:9–19: The three right-most columns of FIG. 2 illustrate methods of combining selected ones of the 32, 6 MHz-wide, 128-QAM-modulated signals with existing terrestrial signals on the cable network 26. The second left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places one or more of the 32, 6 MHz-wide, 128-QAM-modulated signals within a band between about 804 MHz and 996 MHz directly above the common CATV channels. This configuration can be used with higher grade cable networks that propagate signals at up to 1000 MHz without significant degradation. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1.

Asserted Claims	Williams '873
	To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
14[d] transmitting the composite signal over the single cable from the ODU to the IRDs, wherein the modulation of the transponder signal is not altered by the steps of selecting, combining, and transmitting.	Williams '873 discloses, explicitly and/or inherently, transmitting the composite signal over the single cable from the ODU to the IRDs, wherein the modulation of the transponder signal is not altered by the steps of selecting, combining, and transmitting. *See, e.g.*: Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 1:13–18: The present invention relates generally to signal distribution systems and, more particularly, to audio/visual/data signal distribution systems that distribute satellite signals typically in conjunction with standard terrestrial and/or cable signals to a plurality of individual receivers within one or more multiple dwelling units.



Asserted Claims	Williams '873
	Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 4:4–15: According to another aspect of the present invention, a signal distribution system adapted to receive a composite signal having a multiplicity of transponder signals therein includes a transmodulator that transmodulates a selected one of the transponder signals from a first modulation scheme to a second modulation scheme to produce a transmodulated signal and a transmitter that transmits the transmodulated signal over a communication channel to a plurality of individual receivers. A receiver receives a request signal from each of the plurality of individual receivers and a controller selects the selected transponder signal in response to the request signals. Williams '873 at 4:16–38:

Asserted Claims	Williams '873
	According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 4:39–44: Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 4:45–59: The signal distribution system may include a second receiver adapted to receive a terrestrial signal while the combiner may combine the multiplicity of transmodulated signals with the terrestrial signal to produce the combined signal. Furthermore, a reception device coupled to the communication channel at one of the individual receivers may include a receiver that receives the combined signal, a demodulator that demodulates a portion of the received combined signal and an individual transmitter that transmits one of the request signals to the transmodulator indicating one of the plurality of program

Asserted Claims	Williams '873
	multiplex signals to be transmodulated. If desired, the transmodulator channels may transmodulate between a quadrature phase shift keying (QPSK) modulation scheme and a quadrature amplitude modulation (QAM) scheme, such as a 128-QAM scheme. Williams '873 at 4:60–5:5: According to a still further aspect of the present invention, a method of distributing a subset of a plurality of individual signals associated with a composite signal to multiple individual receivers includes the steps of receiving the composite signal, receiving a request signal from each of the individual receivers and choosing the subset of the plurality of the individual signals to be distributed based on the received request signals. Each of the subset of the plurality of the individual signals is transmodulated from a first modulation scheme to a second modulation scheme and is transmitted over a communication channel to the individual receivers. Williams '873 at 5:59–6:11: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 7:4–23:

Asserted Claims	Williams '873
	Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 9:28–39: In accordance with the present invention, the number of transmodulator channels is less than the number of transponder signals associated with the received satellite or other signal and, in a preferred embodiment, the transmodulator 20 includes up to, but less than, 32 transmodulator channels, each of which includes a switch 53, a tuner 54, a satellite decoder 56, a packetizer 58, a cable encoder 60, and an upconverter 62. Each transmodulator channel decodes and transmodulates one of the 32 received transponder signals associated with the downlink signal in essentially the same manner and, as a result, the operation of only one of the transmodulator channels will be described herein. Williams '873 at 10:40–52: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g., local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the

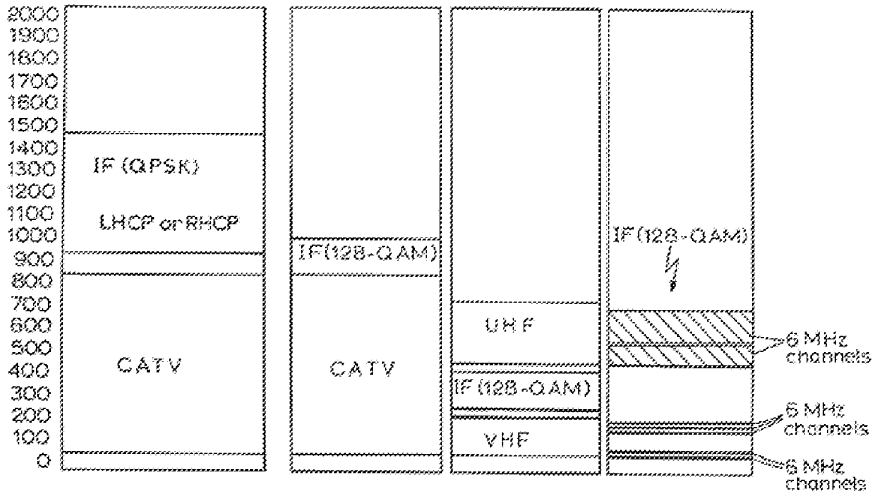
Asserted Claims	Williams '873
	level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Williams '873 at 14:65–15:14: Furthermore, as noted above, modulation techniques besides QAM can be used when transmodulating the decoded satellite signal. Other such modulation techniques may include, for example, any high rate digital modulation techniques such as VSB (vestigial side band), including 8-VSB, 16-VSB etc., or QAM with trellis-coded modulation. Other modulation techniques which may be developed in the future could similarly be used without departing from the spirit and scope of the present invention. In general, the choice of a modulation technique will be driven by the reduction in bandwidth which must be accomplished by the modulation technique and by the noise susceptibility of the modulation technique. If a different modulation technique is used, however, it is understood that a different type of cable encoder will be necessary to properly transmodulate the desired transponder signals (or other received signals) for propagation over the cable network 26. Williams '873 at 15:15–27: Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at Fig. 1:

Asserted Claims	Williams '873
	 FIG. 1 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
15. The method of claim 14 wherein the step of selecting and extracting a transponder signal comprises the step of: filtering a transponder signal with a band pass filter having a bandwidth ranging from 5% to 100% wider than the bandwidth of the transponder signal.	Williams '873 discloses, explicitly and/or inherently, wherein the step of selecting and extracting a transponder signal comprises the step of: filtering a transponder signal with a band pass filter having a bandwidth ranging from 5% to 100% wider than the bandwidth of the transponder signal. *See* claim 14, *supra*. *See, e.g.*:

Asserted Claims	Williams '873
	Williams '873 at 2:15–25: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '873 at 5:59–6:11: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a

Asserted Claims	Williams '873
	selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
16. The method of claim 14 wherein the step of combining comprises frequency translating the selected and extracted transponder channels to a variable frequency before combining.	Williams '873 discloses, explicitly and/or inherently, wherein the step of combining comprises frequency translating the selected and extracted transponder channels to a variable frequency before combining. *See* claim 14, *supra*. *See, e.g.*: Williams '873 at 1:32–46: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units.

Asserted Claims	Williams '873
	Williams '873 at 1:64–2:14: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in-operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz, and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '873 at 2:15–25: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '873 at 2:26–44: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g., between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program



Asserted Claims	Williams '873
	associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 8:20–35: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places one or more of the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20

Asserted Claims	Williams '873
	may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 550 or perhaps 750 MHz without significant degradation. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:10–23: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of a number of summers 64 associated with the transmodulator 20. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the

Asserted Claims	Williams '873
	four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '873 at 10:40–52: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g., local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be

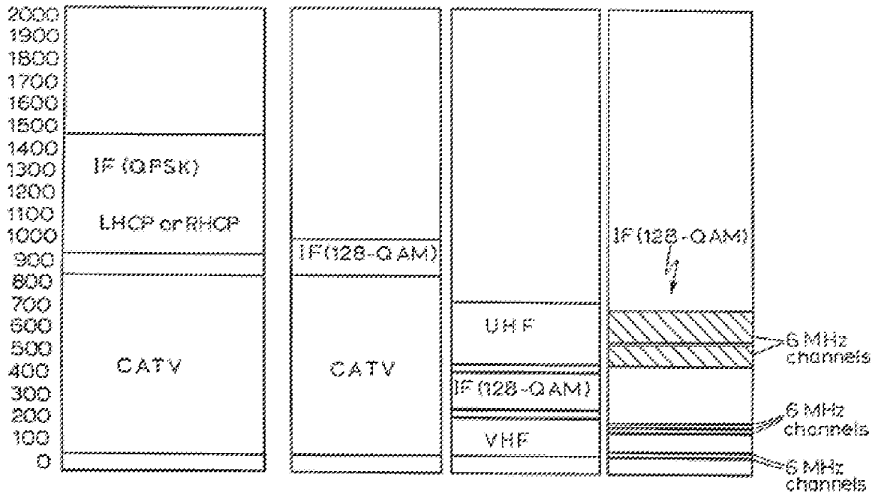
Asserted Claims	Williams '873
	digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner.

Asserted Claims	Williams '873
	Williams '873 at 12:17–34: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '873 at 15:15–27: Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and

Asserted Claims	Williams '873
	transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at Fig. 2:  FIG. 2 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873

Asserted Claims	Williams '873
	with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
17. The method of claim 15 further comprising frequency translating the selected transponder channels to a predetermined frequency before combining.	Williams '873 discloses, explicitly and/or inherently, further comprising frequency translating the selected transponder channels to a predetermined frequency before combining. *See* claim 15, *supra*. *See, e.g.*: Williams '873 at 1:32–46: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '873 at 1:64–2:14: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in-operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz, and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets

Asserted Claims	Williams '873
	associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '873 at 2:15–25: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '873 at 2:26–44: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g., between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD.



Asserted Claims	Williams '873
	Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 8:20–35: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places one or more of the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that

Asserted Claims	Williams '873
	propagate signals at frequencies up to about 550 or perhaps 750 MHz without significant degradation. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:10–23: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of a number of summers 64 associated with the transmodulator 20. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency

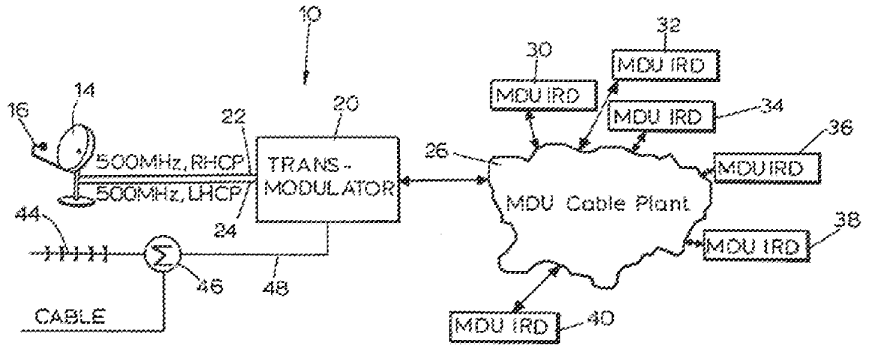
Asserted Claims	Williams '873
	band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '873 at 10:40–52: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g., local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs

Asserted Claims	Williams '873
	30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:17–34: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined

Asserted Claims	Williams '873
	width for all of the desired transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '873 at 15:15–27: Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable

Asserted Claims	Williams '873
	network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at Fig. 2:  FIG. 2 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.

Asserted Claims	Williams '873
18. The method of claim 14 further comprising the step of splitting the composite signal inside a home and distributing to a plurality of IRDs.	Williams '873 discloses, explicitly and/or inherently, further comprising the step of splitting the composite signal inside a home and distributing to a plurality of IRDs. *See* claim 14, *supra*. *See, e.g.*: Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to



Asserted Claims	Williams '873
	a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 4:4–15: According to another aspect of the present invention, a signal distribution system adapted to receive a composite signal having a multiplicity of transponder signals therein includes a transmodulator that transmodulates a selected one of the transponder signals from a first modulation scheme to a second modulation scheme to produce a transmodulated signal and a transmitter that transmits the transmodulated signal over a communication channel to a plurality of individual receivers. A receiver receives a request signal from each of the plurality of individual receivers and a controller selects the selected transponder signal in response to the request signals. Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that

Asserted Claims	Williams '873
	receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 4:39–44: Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 4:45–59: The signal distribution system may include a second receiver adapted to receive a terrestrial signal while the combiner may combine the multiplicity of transmodulated signals with the terrestrial signal to produce the combined signal. Furthermore, a reception device coupled to the communication channel at one of the individual receivers may include a receiver that receives the combined signal, a demodulator that demodulates a portion of the received combined signal and an individual transmitter that transmits one of the request signals to the transmodulator indicating one of the plurality of program multiplex signals to be transmodulated. If desired, the transmodulator channels may transmodulate between a quadrature phase shift keying (QPSK) modulation scheme and a quadrature amplitude modulation (QAM) scheme, such as a 128-QAM scheme. Williams '873 at 4:60–5:5: According to a still further aspect of the present invention, a method of distributing a subset of a plurality of individual signals associated with a composite signal to multiple individual receivers includes the steps of receiving the composite signal, receiving a request signal from each of the individual receivers and choosing the subset of the plurality of the individual signals to be distributed based on the received request signals. Each of the subset of the plurality of the individual signals is transmodulated from a first modulation

Asserted Claims	Williams '873
	scheme to a second modulation scheme and is transmitted over a communication channel to the individual receivers. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator channels to tune to a specific one of the selected transponder signals. The control unit 72 may assign the transmodulator channels to tune to different transponder signals on a first

Asserted Claims	Williams '873
	come, first serve basis, by determining which of the transponder signals have the highest number of active requests associated therewith or using any other desired technique. Williams '873 at 11:22–35: If desired, the control unit 72 may provide a signal via side data to each of the IRDs 30-40 specifying which transponder signals are being transmodulated and transmitted over the cable network 26 and the frequencies at which the transmodulated transponder signals are located on the cable network 26. Also, if desired, when the control unit 72 receives requests for more transponder signals than there are transmodulator channels, the control unit 72 may send a signal to one or more of the IRDs 30-40 indicating that the requested signal cannot be decoded at, the present time because all of the transmodulator channels are being used to transmodulate other transponder signals. This communication may be performed using the cable network 26 or using any other wire or wireless network. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band

Asserted Claims	Williams '873
	associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at 17:21–30: The program multiplexed data is provided to a demultiplexer 120 which is also responsive to the controller 105. The demultiplexer 120, which may be any standard demultiplexer, extracts one of the five to eight A-V programs from the program multiplexed data signal and provides a data stream having data pertaining to the extracted program (as identified by the controller 105) to a decoder having an MPEG video decoder 122, an MPEG audio decoder 123 and/or a data processor 124. Williams '873 at Fig. 1:

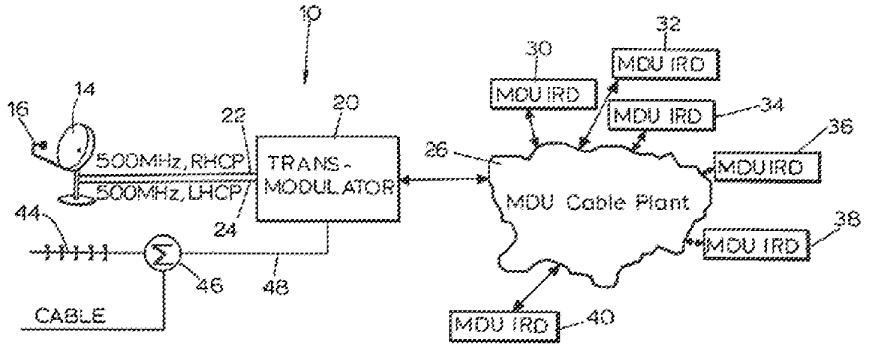
	 FIG. 1 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
19. The method of claim 14 wherein the transponder request signal is transmitted over the cable from an IRD and all IRDs receive the same composite signal.	Williams '873 discloses, explicitly and/or inherently, wherein the transponder request signal is transmitted over the cable from an IRD and all IRDs receive the same composite signal. *See* claim 14, *supra*. *See, e.g.*: Williams '873 at Abstract:



Asserted Claims	Williams '873
	A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 4:39–44:

Asserted Claims	Williams '873
	Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 4:45–59: The signal distribution system may include a second receiver adapted to receive a terrestrial signal while the combiner may combine the multiplicity of transmodulated signals with the terrestrial signal to produce the combined signal. Furthermore, a reception device coupled to the communication channel at one of the individual receivers may include a receiver that receives the combined signal, a demodulator that demodulates a portion of the received combined signal and an individual transmitter that transmits one of the request signals to the transmodulator indicating one of the plurality of program multiplex signals to be transmodulated. If desired, the transmodulator channels may transmodulate between a quadrature phase shift keying (QPSK) modulation scheme and a quadrature amplitude modulation (QAM) scheme, such as a 128-QAM scheme. Williams '873 at 4:60–5:5: According to a still further aspect of the present invention, a method of distributing a subset of a plurality of individual signals associated with a composite signal to multiple individual receivers includes the steps of receiving the composite signal, receiving a request signal from each of the individual receivers and choosing the subset of the plurality of the individual signals to be distributed based on the received request signals. Each of the subset of the plurality of the individual signals is transmodulated from a first modulation scheme to a second modulation scheme and is transmitted over a communication channel to the individual receivers. Williams '873 at 6:35–46: In order to determine which of the received satellite transponder signals should be transmodulated at any particular time, the transmodulator 20 receives and decodes requests

Asserted Claims	Williams '873
	for particular channels or satellite signals from each of the IRDs 30-40 that are active, determines from these requests which of the set of satellite or transponder signals to transmodulate and then tunes to and transmodulates only those selected satellite or transponder signals. The transmodulator sends the updated frequency index to the receiver via side data. If no transponders are available to fulfill the request, the transmodulator sends an error message to the receiver indicating that no transponder is available. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 9:7–27: The L-band RHCP and LHCP signals are each linked to a series of switches 53 associated with a set of transmodulator channels of the transmodulator 20. Preferably, the number of transmodulator channels within the transmodulator 20 is chosen in conjunction with the number of receiver units or IRDs connected to the transmodulator 20. Typically, the fewer

Asserted Claims	Williams '873
	number of IRDs, the fewer number of transmodulator channels that are necessary. Generally speaking, however, the transmodulator 20 will not require more channels than the number of IRDs being supported and, in fact, will typically require less channels because it is not likely that all of the simultaneously operating IRDs being supported by the transmodulator 20 will be tuned to different transponder signals at the same time. If desired, the number of transponder channels may be chosen using any desired statistical analysis, taking into account, for example, the number of supported IRDs, the likelihood that the IRDs will be used at the same time, the likelihood that different IRDs will be tuned to the same satellite transponder signal, etc. Of course, the transmodulator 20 may be designed to be easily upgraded to add more transmodulator channels if necessary. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as

Asserted Claims	Williams '873
	MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator channels to tune to a specific one of the selected transponder signals. The control unit 72 may assign the transmodulator channels to tune to different transponder signals on a first come, first serve basis, by determining which of the transponder signals have the highest number of active requests associated therewith or using any other desired technique. Williams '873 at 11:22–35: If desired, the control unit 72 may provide a signal via side data to each of the IRDs 30-40 specifying which transponder signals are being transmodulated and transmitted over the cable network 26 and the frequencies at which the transmodulated transponder signals are located on the cable network 26. Also, if desired, when the control unit 72 receives requests for more transponder signals than there are transmodulator channels, the control unit 72 may send a signal to one or more of the IRDs 30-40 indicating that the requested signal cannot be decoded at, the present time because all of the transmodulator channels are being used to transmodulate other transponder signals. This communication may be performed using the cable network 26 or using any other wire or wireless network. Williams '873 at 16:5–21:

Asserted Claims	Williams '873
	The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at Fig. 1:  FIG. 1 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873

Asserted Claims	Williams '873
	with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
20. The method of claim 14 wherein the transponder request signal is transmitted over a wireless link to the ODU.	Williams '873 discloses, explicitly and/or inherently, wherein the transponder request signal is transmitted over a wireless link to the ODU. *See* claim 14, *supra*. *See, e.g.*: Williams '873 at 1:20–31: Audio/visual/data (A-V) signal distribution systems generally rely on either a cable network or on free-space propagation for delivering A-V signals, such as television signals, to individual users or subscribers. Cable-based A-V signal distribution systems transmit one or more individual A-V signals or "channels" over wire, while free-space propagation systems transmit one or more channels over-the-air, i.e., in a wireless manner. Most large-scale cable and wireless signal distribution systems broadcast a broadband A-V signal having a plurality of individual A-V signals modulated onto one or more carrier frequencies within a discernable frequency band. Williams '873 at 1:32–46: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to

Asserted Claims	Williams '873
	different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '873 at 2:45–59: Furthermore, the receiving antennas or dishes associated with land-based or satellite-based wireless signal distribution systems are typically large and cumbersome. For example, C-band satellite dishes are generally in the range of four to five feet in diameter and, therefore, require a large amount of operating space. As a result, it can be difficult, if not practically impossible, to install a receiving antenna for each individual unit within a multiple dwelling unit (MDU), such as an apartment, condominium or townhome complex. Reception of a particular satellite signal is made even more difficult in MDUs when, as is generally the case, some of the individual dwelling units therein do not have any walls or outside exposure facing the direction in which the receiving antenna must be pointed, or these dwelling units are shadowed by surrounding buildings or other obstructions. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which

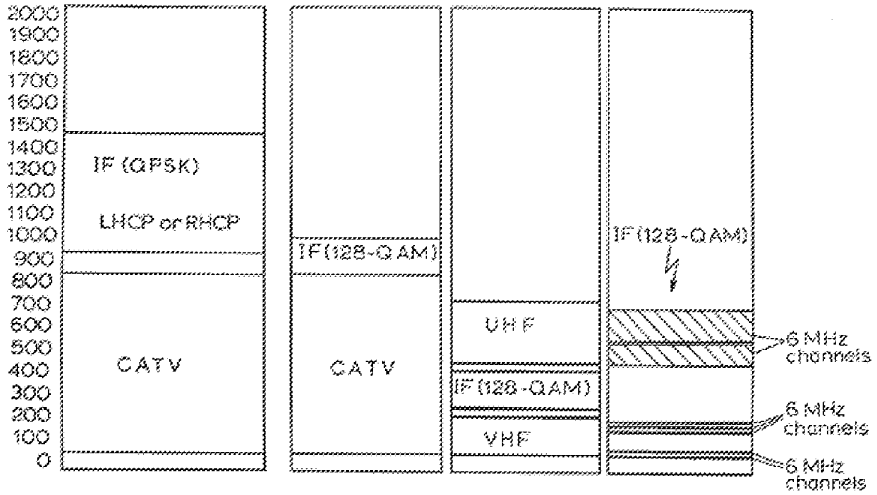
Asserted Claims	Williams '873
	uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 5:30–44: By the way of example only, the signal distribution system of the present invention is described herein as redistributing a broadband Ku-band satellite signal (comprising up to 32, QPSK-modulated transponder signals transmitted from one or more satellites at a carrier frequency band centered around approximately 12.45 GHz) to receiver units within an MDU. It is understood however, that the signal distribution system of the present invention can be used to redistribute any other type of satellite or land-based wireless signal. The term program multiplex (PM) signal is used herein to describe any single or multiplex of purely visual (such as video), purely audio, or purely data signals as well as a signal comprising any combination of audio, visual, data or other signals including, for example, television signals, digital data signals, etc. Williams '873 at 6:12–34: The transmodulator 20 remodulates or transmodulates a subset of the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to any lower bandwidth. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes and/or by remodulating less than all of the received transponder signals associated with the composite signal. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal having less than all of the received transponder signals on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the

Asserted Claims	Williams '873
	transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other

Asserted Claims	Williams '873
	communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:22–35: If desired, the control unit 72 may provide a signal via side data to each of the IRDs 30-40 specifying which transponder signals are being transmodulated and transmitted over the cable network 26 and the frequencies at which the transmodulated transponder signals are located on the cable network 26. Also, if desired, when the control unit 72 receives requests for more transponder signals than there are transmodulator channels, the control unit 72 may send a signal to one or more of the IRDs 30-40 indicating that the requested signal cannot be decoded at, the present time because all of the transmodulator channels

Asserted Claims	Williams '873
	are being used to transmodulate other transponder signals. This communication may be performed using the cable network 26 or using any other wire or wireless network. To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
21[a] 21. The method of claim 14 further comprising the steps of: frequency translating the selected transponder channels to a variable frequency before combining; and	Williams '873 discloses, explicitly and/or inherently, frequency translating the selected transponder channels to a variable frequency before combining. *See* claims 14, 16, *supra*. *See, e.g.*: Williams '873 at 1:32–46: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '873 at 1:64–2:14:

Asserted Claims	Williams '873
	Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in-operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz, and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '873 at 2:15–25: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '873 at 2:26–44: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g., between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device



Asserted Claims	Williams '873
	for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 8:20–35: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places one or more of the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF

Asserted Claims	Williams '873
	band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 550 or perhaps 750 MHz without significant degradation. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:10–23: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of a number of summers 64 associated with the transmodulator 20. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide

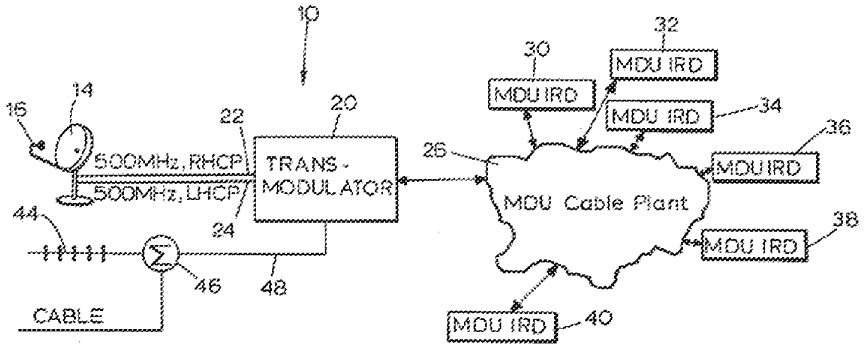
Asserted Claims	Williams '873
	transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '873 at 10:40–52: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g., local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the

Asserted Claims	Williams '873
	control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:17–34:

Asserted Claims	Williams '873
	If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '873 at 15:15–27: Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of

Asserted Claims	Williams '873
	the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at Fig. 2:  FIG. 2 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.

Asserted Claims	Williams '873
21[b] splitting the composite signal inside a home and distributing to a plurality of IRDs.	Williams '873 discloses, explicitly and/or inherently, splitting the composite signal inside a home and distributing to a plurality of IRDs. *See* claims 14, 18, *supra*. *See, e.g.*: Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to



Asserted Claims	Williams '873
	a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 4:4–15: According to another aspect of the present invention, a signal distribution system adapted to receive a composite signal having a multiplicity of transponder signals therein includes a transmodulator that transmodulates a selected one of the transponder signals from a first modulation scheme to a second modulation scheme to produce a transmodulated signal and a transmitter that transmits the transmodulated signal over a communication channel to a plurality of individual receivers. A receiver receives a request signal from each of the plurality of individual receivers and a controller selects the selected transponder signal in response to the request signals. Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that

Asserted Claims	Williams '873
	receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 4:39–44: Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 4:45–59: The signal distribution system may include a second receiver adapted to receive a terrestrial signal while the combiner may combine the multiplicity of transmodulated signals with the terrestrial signal to produce the combined signal. Furthermore, a reception device coupled to the communication channel at one of the individual receivers may include a receiver that receives the combined signal, a demodulator that demodulates a portion of the received combined signal and an individual transmitter that transmits one of the request signals to the transmodulator indicating one of the plurality of program multiplex signals to be transmodulated. If desired, the transmodulator channels may transmodulate between a quadrature phase shift keying (QPSK) modulation scheme and a quadrature amplitude modulation (QAM) scheme, such as a 128-QAM scheme. Williams '873 at 4:60–5:5: According to a still further aspect of the present invention, a method of distributing a subset of a plurality of individual signals associated with a composite signal to multiple individual receivers includes the steps of receiving the composite signal, receiving a request signal from each of the individual receivers and choosing the subset of the plurality of the individual signals to be distributed based on the received request signals. Each of the subset of the plurality of the individual signals is transmodulated from a first modulation

Asserted Claims	Williams '873
	scheme to a second modulation scheme and is transmitted over a communication channel to the individual receivers. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator channels to tune to a specific one of the selected transponder signals. The control unit 72 may assign the transmodulator channels to tune to different transponder signals on a first

Asserted Claims	Williams '873
	come, first serve basis, by determining which of the transponder signals have the highest number of active requests associated therewith or using any other desired technique. Williams '873 at 11:22–35: If desired, the control unit 72 may provide a signal via side data to each of the IRDs 30-40 specifying which transponder signals are being transmodulated and transmitted over the cable network 26 and the frequencies at which the transmodulated transponder signals are located on the cable network 26. Also, if desired, when the control unit 72 receives requests for more transponder signals than there are transmodulator channels, the control unit 72 may send a signal to one or more of the IRDs 30-40 indicating that the requested signal cannot be decoded at, the present time because all of the transmodulator channels are being used to transmodulate other transponder signals. This communication may be performed using the cable network 26 or using any other wire or wireless network. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band

Asserted Claims	Williams '873
	associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at 17:21–30: The program multiplexed data is provided to a demultiplexer 120 which is also responsive to the controller 105. The demultiplexer 120, which may be any standard demultiplexer, extracts one of the five to eight A-V programs from the program multiplexed data signal and provides a data stream having data pertaining to the extracted program (as identified by the controller 105) to a decoder having an MPEG video decoder 122, an MPEG audio decoder 123 and/or a data processor 124.

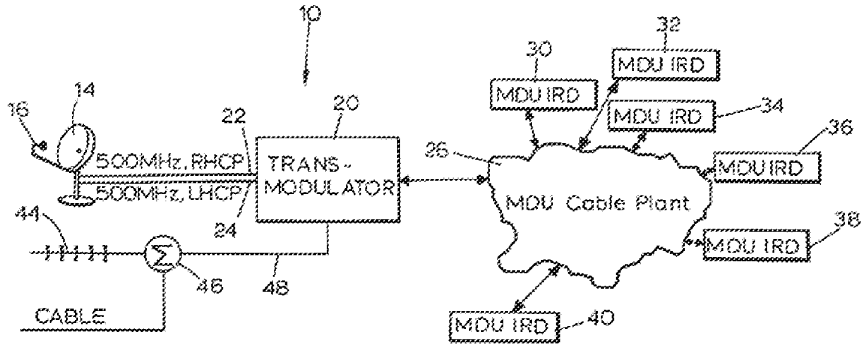
22. The method of claim 21 wherein the transponder request signal is transmitted over the cable from an IRD.	Williams '873 discloses, explicitly and/or inherently, wherein the transponder request signal is transmitted over the cable from an IRD. *See* claims 19, 21, *supra*. *See, e.g.*:



Asserted Claims	Williams '873
	Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate.

Asserted Claims	Williams '873
	Williams '873 at 4:39–44: Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 4:45–59: The signal distribution system may include a second receiver adapted to receive a terrestrial signal while the combiner may combine the multiplicity of transmodulated signals with the terrestrial signal to produce the combined signal. Furthermore, a reception device coupled to the communication channel at one of the individual receivers may include a receiver that receives the combined signal, a demodulator that demodulates a portion of the received combined signal and an individual transmitter that transmits one of the request signals to the transmodulator indicating one of the plurality of program multiplex signals to be transmodulated. If desired, the transmodulator channels may transmodulate between a quadrature phase shift keying (QPSK) modulation scheme and a quadrature amplitude modulation (QAM) scheme, such as a 128-QAM scheme. Williams '873 at 4:60–5:5: According to a still further aspect of the present invention, a method of distributing a subset of a plurality of individual signals associated with a composite signal to multiple individual receivers includes the steps of receiving the composite signal, receiving a request signal from each of the individual receivers and choosing the subset of the plurality of the individual signals to be distributed based on the received request signals. Each of the subset of the plurality of the individual signals is transmodulated from a first modulation scheme to a second modulation scheme and is transmitted over a communication channel to the individual receivers. Williams '873 at 6:35–46:

Asserted Claims	Williams '873
	In order to determine which of the received satellite transponder signals should be transmodulated at any particular time, the transmodulator 20 receives and decodes requests for particular channels or satellite signals from each of the IRDs 30-40 that are active, determines from these requests which of the set of satellite or transponder signals to transmodulate and then tunes to and transmodulates only those selected satellite or transponder signals. The transmodulator sends the updated frequency index to the receiver via side data. If no transponders are available to fulfill the request, the transmodulator sends an error message to the receiver indicating that no transponder is available. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 9:7–27: The L-band RHCP and LHCP signals are each linked to a series of switches 53 associated with a set of transmodulator channels of the transmodulator 20. Preferably, the number of

Asserted Claims	Williams '873
	transmodulator channels within the transmodulator 20 is chosen in conjunction with the number of receiver units or IRDs connected to the transmodulator 20. Typically, the fewer number of IRDs, the fewer number of transmodulator channels that are necessary. Generally speaking, however, the transmodulator 20 will not require more channels than the number of IRDs being supported and, in fact, will typically require less channels because it is not likely that all of the simultaneously operating IRDs being supported by the transmodulator 20 will be tuned to different transponder signals at the same time. If desired, the number of transponder channels may be chosen using any desired statistical analysis, taking into account, for example, the number of supported IRDs, the likelihood that the IRDs will be used at the same time, the likelihood that different IRDs will be tuned to the same satellite transponder signal, etc. Of course, the transmodulator 20 may be designed to be easily upgraded to add more transmodulator channels if necessary. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other

Asserted Claims	Williams '873
	wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator channels to tune to a specific one of the selected transponder signals. The control unit 72 may assign the transmodulator channels to tune to different transponder signals on a first come, first serve basis, by determining which of the transponder signals have the highest number of active requests associated therewith or using any other desired technique. Williams '873 at 11:22–35: If desired, the control unit 72 may provide a signal via side data to each of the IRDs 30-40 specifying which transponder signals are being transmodulated and transmitted over the cable network 26 and the frequencies at which the transmodulated transponder signals are located on the cable network 26. Also, if desired, when the control unit 72 receives requests for more transponder signals than there are transmodulator channels, the control unit 72 may send a signal to one or more of the IRDs 30-40 indicating that the requested signal cannot be decoded at, the present time because all of the transmodulator channels are being used to transmodulate other transponder signals. This communication may be performed using the cable network 26 or using any other wire or wireless network.

Asserted Claims	Williams '873
	Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at Fig. 1:  FIG. 1

Asserted Claims	Williams '873
	To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
23. The method of claim 21 wherein the transponder request signal is transmitted over a wireless link to the ODU.	Williams '873 discloses, explicitly and/or inherently, wherein the transponder request signal is transmitted over a wireless link to the ODU. *See* claims 20, 21, *supra*. *See, e.g.*: Williams '873 at 1:20–31: Audio/visual/data (A-V) signal distribution systems generally rely on either a cable network or on free-space propagation for delivering A-V signals, such as television signals, to individual users or subscribers. Cable-based A-V signal distribution systems transmit one or more individual A-V signals or "channels" over wire, while free-space propagation systems transmit one or more channels over-the-air, i.e., in a wireless manner. Most large-scale cable and wireless signal distribution systems broadcast a broadband A-V signal having a plurality of individual A-V signals modulated onto one or more carrier frequencies within a discernable frequency band. Williams '873 at 1:32–46: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number

Asserted Claims	Williams '873
	of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '873 at 2:45–59: Furthermore, the receiving antennas or dishes associated with land-based or satellite-based wireless signal distribution systems are typically large and cumbersome. For example, C-band satellite dishes are generally in the range of four to five feet in diameter and, therefore, require a large amount of operating space. As a result, it can be difficult, if not practically impossible, to install a receiving antenna for each individual unit within a multiple dwelling unit (MDU), such as an apartment, condominium or townhome complex. Reception of a particular satellite signal is made even more difficult in MDUs when, as is generally the case, some of the individual dwelling units therein do not have any walls or outside exposure facing the direction in which the receiving antenna must be pointed, or these dwelling units are shadowed by surrounding buildings or other obstructions. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or

Asserted Claims	Williams '873
	display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 5:30–44: By the way of example only, the signal distribution system of the present invention is described herein as redistributing a broadband Ku-band satellite signal (comprising up to 32, QPSK-modulated transponder signals transmitted from one or more satellites at a carrier frequency band centered around approximately 12.45 GHz) to receiver units within an MDU. It is understood however, that the signal distribution system of the present invention can be used to redistribute any other type of satellite or land-based wireless signal. The term program multiplex (PM) signal is used herein to describe any single or multiplex of purely visual (such as video), purely audio, or purely data signals as well as a signal comprising any combination of audio, visual, data or other signals including, for example, television signals, digital data signals, etc. Williams '873 at 6:12–34: The transmodulator 20 remodulates or transmodulates a subset of the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to any lower bandwidth. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes and/or by remodulating less than all of the received transponder signals associated with the composite signal. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal having less than all of the received transponder signals on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel

Asserted Claims	Williams '873
	(including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the

Asserted Claims	Williams '873
	cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:22–35: If desired, the control unit 72 may provide a signal via side data to each of the IRDs 30-40 specifying which transponder signals are being transmodulated and transmitted over the cable network 26 and the frequencies at which the transmodulated transponder signals are located on the cable network 26. Also, if desired, when the control unit 72 receives requests for more transponder signals than there are transmodulator channels, the control

Asserted Claims	Williams '873
	unit 72 may send a signal to one or more of the IRDs 30-40 indicating that the requested signal cannot be decoded at, the present time because all of the transmodulator channels are being used to transmodulate other transponder signals. This communication may be performed using the cable network 26 or using any other wire or wireless network. To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
34. The method of claim 14, wherein selecting and extracting comprises applying a pass band filter transfer function to the digitized broadband signal.	Williams '873 discloses, explicitly and/or inherently, wherein selecting and extracting comprises applying a pass band filter transfer function to the digitized broadband signal. *See* claims 14, 15, *supra*. *See, e.g.*: Williams '873 at 2:15–25: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '873 at 5:59–6:11:

Asserted Claims	Williams '873
	The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
35. The method of claim 14, further comprising converting the selected signal to an analog signal using a	Williams '873 discloses, explicitly and/or inherently, further comprising converting the selected signal to an analog signal using a digital to analog converter prior to combining.

Asserted Claims	Williams '873
digital to analog converter prior to combining.	*See* claim 14, *supra*. *See, e.g.*: Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 17:31–52: The MPEG video decoder 122, which may be any standard MPEG2 video decoder commonly known in the art, operates to produce a digital video signal from the received bit stream and provides this digital signal to an NTSC encoder 125. The NTSC encoder 125, which may be any standard encoder, converts the received digital signal into an analog NTSC video signal and provides this signal to a television set 126 for display on the television screen, as is commonly known in the art. If desired, the NTSC encoder 125 may also receive signals from the controller 105 for display on the T.V. 126. Such signals may indicate to a user that, for example, a requested channel is not presently available on the

Asserted Claims	Williams '873
	system because the transmodulator 20 cannot assign a transmodulator channel to the satellite transponder signal associated with the requested channel at the present time. Of course, the controller 105 may have similar connections to the MPEG audio decoder 123, the MPEG video decoder 122 and/or the data processor 124. Other standard video encoders including, for example, PAL, SECAM, etc., may also be used alone or in combination. Williams '873 at 17:53–18:4: The MPEG audio decoder 123, which may be any standard audio decoder commonly known in the art, produces a digital audio signal from the received bit stream, and provides this audio bit stream to a D/A converter 127 which, in turn, provides an analog audio signal to the television set 126 for use in conjunction with the video signal developed by the NTSC encoder 125. The data processor 124 performs independent data processing or data functions on data within the decoded signal. The data processor 124 may, for example, decode, display and/or run web pages, software programs, etc. delivered via the satellite communication channel. In addition or in the alternative, other video, audio and/or data signals may be processed or output in known manners. Likewise, terrestrial signals may be diplexed off of the cable network 26 and provided to a tuner associated with a user television, VCR, etc. for demodulation in manners known in the art. To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
36. The method of claim 14, wherein the combining is performed in the digital domain.	Williams '873 discloses, explicitly and/or inherently, wherein the combining is performed in the digital domain. *See* claim 14, *supra*.

Asserted Claims	Williams '873
	See, e.g.: Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which

Asserted Claims	Williams '873
	uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 4:39–44: Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 4:45–59: The signal distribution system may include a second receiver adapted to receive a terrestrial signal while the combiner may combine the multiplicity of transmodulated signals with the terrestrial signal to produce the combined signal. Furthermore, a reception

Asserted Claims	Williams '873
	device coupled to the communication channel at one of the individual receivers may include a receiver that receives the combined signal, a demodulator that demodulates a portion of the received combined signal and an individual transmitter that transmits one of the request signals to the transmodulator indicating one of the plurality of program multiplex signals to be transmodulated. If desired, the transmodulator channels may transmodulate between a quadrature phase shift keying (QPSK) modulation scheme and a quadrature amplitude modulation (QAM) scheme, such as a 128-QAM scheme. Williams '873 at 5:30–44: By the way of example only, the signal distribution system of the present invention is described herein as redistributing a broadband Ku-band satellite signal (comprising up to 32, QPSK-modulated transponder signals transmitted from one or more satellites at a carrier frequency band centered around approximately 12.45 GHz) to receiver units within an MDU. It is understood however, that the signal distribution system of the present invention can be used to redistribute any other type of satellite or land-based wireless signal. The term program multiplex (PM) signal is used herein to describe any single or multiplex of purely visual (such as video), purely audio, or purely data signals as well as a signal comprising any combination of audio, visual, data or other signals including, for example, television signals, digital data signals, etc. Williams '873 at 7:48–8:8: Referring now to FIG. 2, representative methods of combining the transmodulated transponder signals along with terrestrial signals on the cable network 26 are illustrated. The left-most column of FIG. 2 illustrates a previously known method of placing QPSK-modulated signals along with terrestrial signals on a cable network. According to this scheme, all existing terrestrial signals (including cable TV signals) are distributed at, for example, VHF and UHF carrier frequencies below 950 MHz while one of the 500 MHz-wide QPSK-modulated signals (associated with either the LHCP or the RHCP component of the satellite signal) is placed directly on the cable network at the unused band between about 950 MHz and 1450 MHz. A major problem with this configuration is that only the

Asserted Claims	Williams '873
	RHCP or the LHCP transponder signals can be placed on a 1450 MHz capable cable network at any given time which, in turn, prevents IRDs within an MDU from decoding or receiving channels associated with the other of the LHCP or the RHCP transponder signals. While this problem can be overcome by running two cable lines throughout an MDU or by utilizing a high frequency cable plant capable of approximately 2 GHz or greater bandwidth, these solutions require additional equipment and expense and are not adaptable to most existing cable plants now in use. Furthermore, the signals provided at the 950 MHz to 1450 MHz band can be severely degraded by the cable plant due to the poor high frequency propagation properties of many existing cable plants, especially older cable plants. Williams '873 at 8:9–19: The three right-most columns of FIG. 2 illustrate methods of combining selected ones of the 32, 6 MHz-wide, 128-QAM-modulated signals with existing terrestrial signals on the cable network 26. The second left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places one or more of the 32, 6 MHz-wide, 128-QAM-modulated signals within a band between about 804 MHz and 996 MHz directly above the common CATV channels. This configuration can be used with higher grade cable networks that propagate signals at up to 1000 MHz without significant degradation. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each

Asserted Claims	Williams '873
	other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
37. The method of claim 17, wherein frequency translating comprises using a digital mixer to apply a rotating phasor to the data samples to translate their frequency.	Williams '873 discloses, explicitly and/or inherently, wherein frequency translating comprises using a digital mixer to apply a rotating phasor to the data samples to translate their frequency. *See* claim 17, *supra*. *See, e.g.*: Williams '873 at 1:32–46: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units.

Asserted Claims	Williams '873
	Williams '873 at 2:26–44: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g., between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable

Asserted Claims	Williams '873
	network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 8:20–35: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places one or more of the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 550 or perhaps 750 MHz without significant degradation. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:10–23: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to

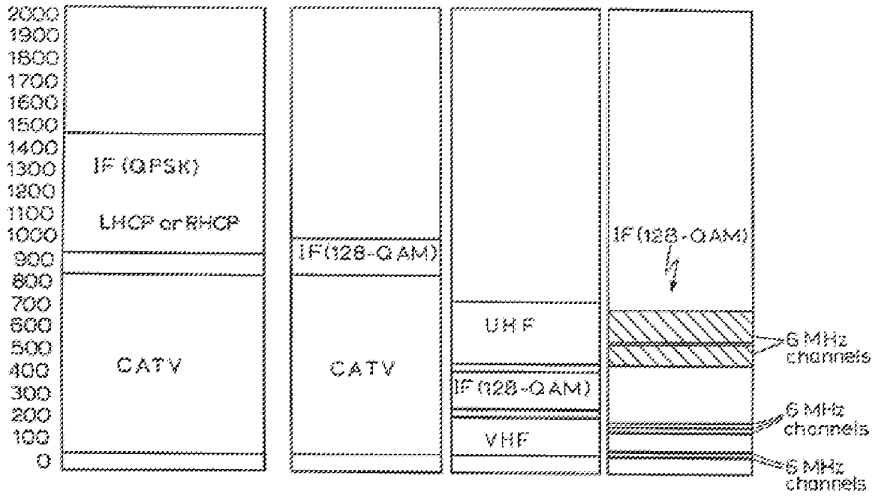
Asserted Claims	Williams '873
	an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of a number of summers 64 associated with the transmodulator 20. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial

Asserted Claims	Williams '873
	signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:17–34: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria.

Asserted Claims	Williams '873
	Williams '873 at 15:15–27: Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.

Asserted Claims	Williams '873
38. The method of claim 14, further comprising frequency translating the digitized broadband signal prior to selecting and extracting transponder signal.	Williams '873 discloses, explicitly and/or inherently, further comprising frequency translating the digitized broadband signal prior to selecting and extracting transponder signal. *See* claims 14, *supra*. *See, e.g.*: Williams '873 at 1:32–46: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '873 at 1:64–2:14: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in-operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz, and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder

Asserted Claims	Williams '873
	signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '873 at 2:15–25: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '873 at 2:26–44: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g., between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V



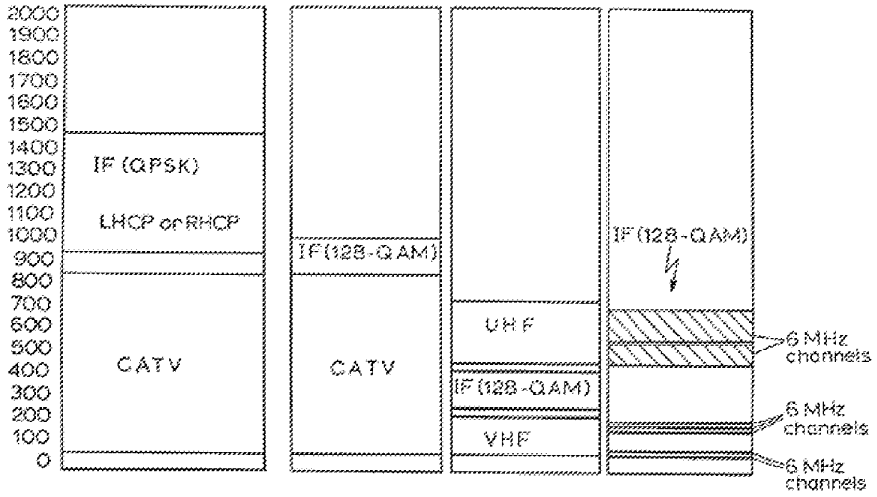
Asserted Claims	Williams '873
	channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 8:20–35: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places one or more of the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 550 or perhaps 750 MHz without significant degradation. Williams '873 at 9:40–48:

Asserted Claims	Williams '873
	The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:10–23: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of a number of summers 64 associated with the transmodulator 20. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1.

Asserted Claims	Williams '873
	Williams '873 at 10:40–52: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g., local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:36–67:

Asserted Claims	Williams '873
	The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:17–34: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the transmodulated signals. In the case in which one or more of the terrestrial signals or the

Asserted Claims	Williams '873
	satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '873 at 15:15–27: Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners.



Asserted Claims	Williams '873
	At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '873 at 2:26–44: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g., between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals

Asserted Claims	Williams '873
	and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1.

Asserted Claims	Williams '873
	Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at Fig. 2:

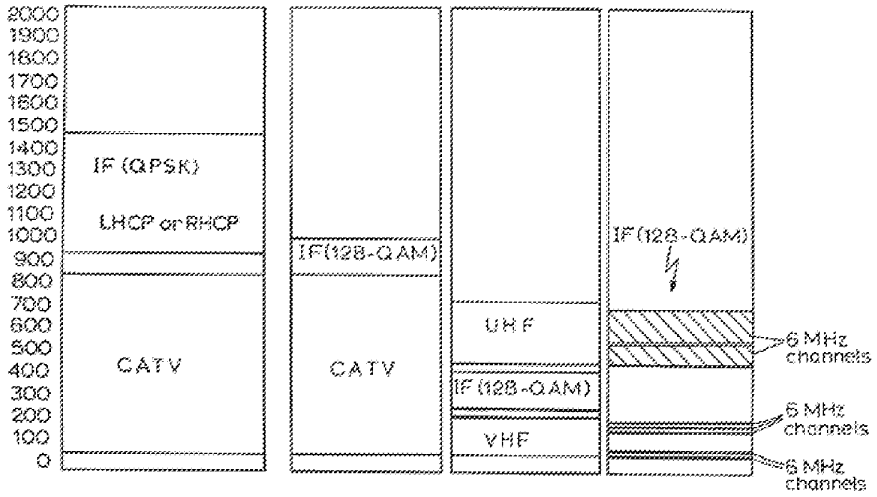
	 FIG. 2 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
40. The method of claim 14, further comprising maintaining a channel translation table at the outdoor unit, the channel translation table specifying assigned frequency slots for transponder channels in the composite signal.	Williams '873 discloses, explicitly and/or inherently, further comprising maintaining a channel translation table at the outdoor unit, the channel translation table specifying assigned frequency slots for transponder channels in the composite signal. *See* claim 14, *supra*. *See, e.g.*:

Asserted Claims	Williams '873
	Williams '873 at 1:64–2:14: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in-operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz, and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate.

Asserted Claims	Williams '873
	Williams '873 at 5:59–6:11: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 6:12–34: The transmodulator 20 remodulates or transmodulates a subset of the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to any lower bandwidth. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes and/or by remodulating less than all of the received transponder signals associated with the composite signal. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal having less than all of the received transponder signals on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the



Asserted Claims	Williams '873
	transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact,

Asserted Claims	Williams '873
	in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 7:48–8:8: Referring now to FIG. 2, representative methods of combining the transmodulated transponder signals along with terrestrial signals on the cable network 26 are illustrated. The left-most column of FIG. 2 illustrates a previously known method of placing QPSK-modulated signals along with terrestrial signals on a cable network. According to this scheme, all existing terrestrial signals (including cable TV signals) are distributed at, for example, VHF and UHF carrier frequencies below 950 MHz while one of the 500 MHz-wide QPSK-modulated signals (associated with either the LHCP or the RHCP component of the satellite signal) is placed directly on the cable network at the unused band between about 950 MHz and 1450 MHz. A major problem with this configuration is that only the RHCP or the LHCP transponder signals can be placed on a 1450 MHz capable cable network at any given time which, in turn, prevents IRDs within an MDU from decoding or receiving channels associated with the other of the LHCP or the RHCP transponder signals. While this problem can be overcome by running two cable lines throughout an MDU or by utilizing a high frequency cable plant capable of approximately 2 GHz or greater bandwidth, these solutions require additional equipment and expense and are not adaptable to most existing cable plants now in use. Furthermore, the signals provided at the 950 MHz to 1450 MHz band can be severely degraded by the cable plant due to the poor high frequency propagation properties of many existing cable plants, especially older cable plants. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the

Asserted Claims	Williams '873
	four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency

Asserted Claims	Williams '873
	sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:1–6: After the control unit 72 identifies all of the empty or unused frequency bands, this information is preferably stored in non-volatile memory. Operator selection (e.g., by means of a keypad) may also be utilized to select or de-select frequency bands, either alone or in conjunction with an automated system. Williams '873 at 12:7–16: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the transmodulated signals and, if so, identify that band for use by a specific one or more of the transmodulated signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all of the transmodulated signals. Williams '873 at 12:17–34: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on

Asserted Claims	Williams '873
	the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '873 at 12:35–47: A transmodulator control panel 74 is coupled to the control unit 72 and, preferably, includes signal strength measurement devices that indicate the relative strength of each of the satellite signals and/or each of the terrestrial signals input to the transmodulator 20. The control panel 74 may also allow an operator to choose default frequency locations for each of the transmodulated and/or terrestrial signals and may include controls that permit an installer to select the carrier frequency bands for any number of the transmodulated and/or terrestrial signals. Of course, the transmodulator control panel 74 and the control unit 72 may perform any other desired functions with respect to the transmodulator 20. Williams '873 at 15:53–16:4: The IRD 30 may initially scan all the channels from, for example, low carrier frequencies to high carrier frequencies, to locate the frequency bands or channels used by the selected ones of the transmodulated signals and then assign channel numbers to these located signals based on a predetermined ordering scheme used by the transmodulator 20. However, as noted above, the transmodulator 20 may actively signal the channel locations, ordering, frequency assignments, etc. of the transmodulated satellite signals and/or terrestrial signals via a communication channel (using side data) established over, for example, the cable network 26. Such a communication channel may comprise a low-speed channel that uses uncoded bits of the sync and error code bytes within the, for example, 188 byte data packets, and may be used to deliver any desired information to the IRD 30 over time, i.e., using a large number of the 188 byte data packets. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and

Asserted Claims	Williams '873
	transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at Fig. 2:  FIG. 2 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873

Asserted Claims	Williams '873
	with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
41. The method of claim 38, further comprising providing the channel translation table to the IRD to allow the IRD to tune to a desired selected translated transponder channel.	Williams '873 discloses, explicitly and/or inherently, further comprising providing the channel translation table to the IRD to allow the IRD to tune to a desired selected translated transponder channel. *See* claim 38, *supra*. *See, e.g.*: Williams '873 at 1:64–2:14: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in-operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz, and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels

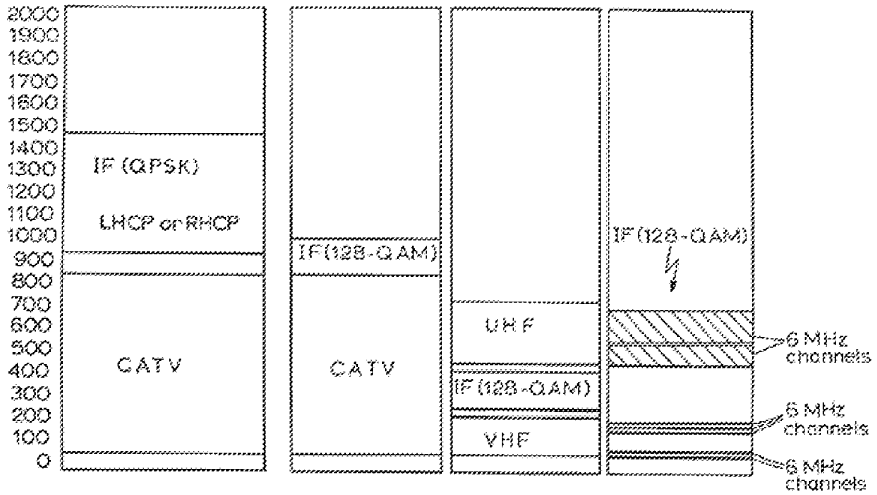
Asserted Claims	Williams '873
	coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 5:59–6:11: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 6:12–34: The transmodulator 20 remodulates or transmodulates a subset of the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth

Asserted Claims	Williams '873
	of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to any lower bandwidth. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes and/or by remodulating less than all of the received transponder signals associated with the composite signal. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal having less than all of the received transponder signals on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '873 at 6:35–46: In order to determine which of the received satellite transponder signals should be transmodulated at any particular time, the transmodulator 20 receives and decodes requests for particular channels or satellite signals from each of the IRDs 30-40 that are active, determines from these requests which of the set of satellite or transponder signals to transmodulate and then tunes to and transmodulates only those selected satellite or transponder signals. The transmodulator sends the updated frequency index to the receiver via side data. If no transponders are available to fulfill the request, the transmodulator sends an error message to the receiver indicating that no transponder is available. Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and

Asserted Claims	Williams '873
	places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 7:24–47:

Asserted Claims	Williams '873
	Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 7:48–8:8: Referring now to FIG. 2, representative methods of combining the transmodulated transponder signals along with terrestrial signals on the cable network 26 are illustrated. The left-most column of FIG. 2 illustrates a previously known method of placing QPSK-modulated signals along with terrestrial signals on a cable network. According to this scheme, all existing terrestrial signals (including cable TV signals) are distributed at, for example, VHF and UHF carrier frequencies below 950 MHz while one of the 500 MHz-wide QPSK-modulated signals (associated with either the LHCP or the RHCP component of the satellite signal) is placed directly on the cable network at the unused band between about 950 MHz and 1450 MHz. A major problem with this configuration is that only the RHCP or the LHCP transponder signals can be placed on a 1450 MHz capable cable network at any given time which, in turn, prevents IRDs within an MDU from decoding or receiving channels associated with the other of the LHCP or the RHCP transponder signals. While this problem can be overcome by running two cable lines throughout an

Asserted Claims	Williams '873
	MDU or by utilizing a high frequency cable plant capable of approximately 2 GHz or greater bandwidth, these solutions require additional equipment and expense and are not adaptable to most existing cable plants now in use. Furthermore, the signals provided at the 950 MHz to 1450 MHz band can be severely degraded by the cable plant due to the poor high frequency propagation properties of many existing cable plants, especially older cable plants. Williams '873 at 9:28–39: In accordance with the present invention, the number of transmodulator channels is less than the number of transponder signals associated with the received satellite or other signal and, in a preferred embodiment, the transmodulator 20 includes up to, but less than, 32 transmodulator channels, each of which includes a switch 53, a tuner 54, a satellite decoder 56, a packetizer 58, a cable encoder 60, and an upconverter 62. Each transmodulator channel decodes and transmodulates one of the 32 received transponder signals associated with the downlink signal in essentially the same manner and, as a result, the operation of only one of the transmodulator channels will be described herein. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide



Asserted Claims	Williams '873
	transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator

Asserted Claims	Williams '873
	channels to tune to a specific one of the selected transponder signals. The control unit 72 may assign the transmodulator channels to tune to different transponder signals on a first come, first serve basis, by determining which of the transponder signals have the highest number of active requests associated therewith or using any other desired technique. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:1–6:

Asserted Claims	Williams '873
	After the control unit 72 identifies all of the empty or unused frequency bands, this information is preferably stored in non-volatile memory. Operator selection (e.g., by means of a keypad) may also be utilized to select or de-select frequency bands, either alone or in conjunction with an automated system. Williams '873 at 12:7–16: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the transmodulated signals and, if so, identify that band for use by a specific one or more of the transmodulated signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all of the transmodulated signals. Williams '873 at 12:17–34: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '873 at 12:35–47:

Asserted Claims	Williams '873
	A transmodulator control panel 74 is coupled to the control unit 72 and, preferably, includes signal strength measurement devices that indicate the relative strength of each of the satellite signals and/or each of the terrestrial signals input to the transmodulator 20. The control panel 74 may also allow an operator to choose default frequency locations for each of the transmodulated and/or terrestrial signals and may include controls that permit an installer to select the carrier frequency bands for any number of the transmodulated and/or terrestrial signals. Of course, the transmodulator control panel 74 and the control unit 72 may perform any other desired functions with respect to the transmodulator 20. Williams '873 at 15:15–27: Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at 15:53–16:4: The IRD 30 may initially scan all the channels from, for example, low carrier frequencies to high carrier frequencies, to locate the frequency bands or channels used by the selected ones of the transmodulated signals and then assign channel numbers to these located signals based on a predetermined ordering scheme used by the transmodulator 20. However, as noted above, the transmodulator 20 may actively signal the channel locations, ordering, frequency assignments, etc. of the transmodulated satellite signals and/or terrestrial signals via a communication channel (using side data) established over, for example, the cable network 26. Such a communication channel may comprise a low-speed channel that uses uncoded bits of the sync and error code bytes within the, for example,

Asserted Claims	Williams '873
	188 byte data packets, and may be used to deliver any desired information to the IRD 30 over time, i.e., using a large number of the 188 byte data packets. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at 16:22–42: The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This

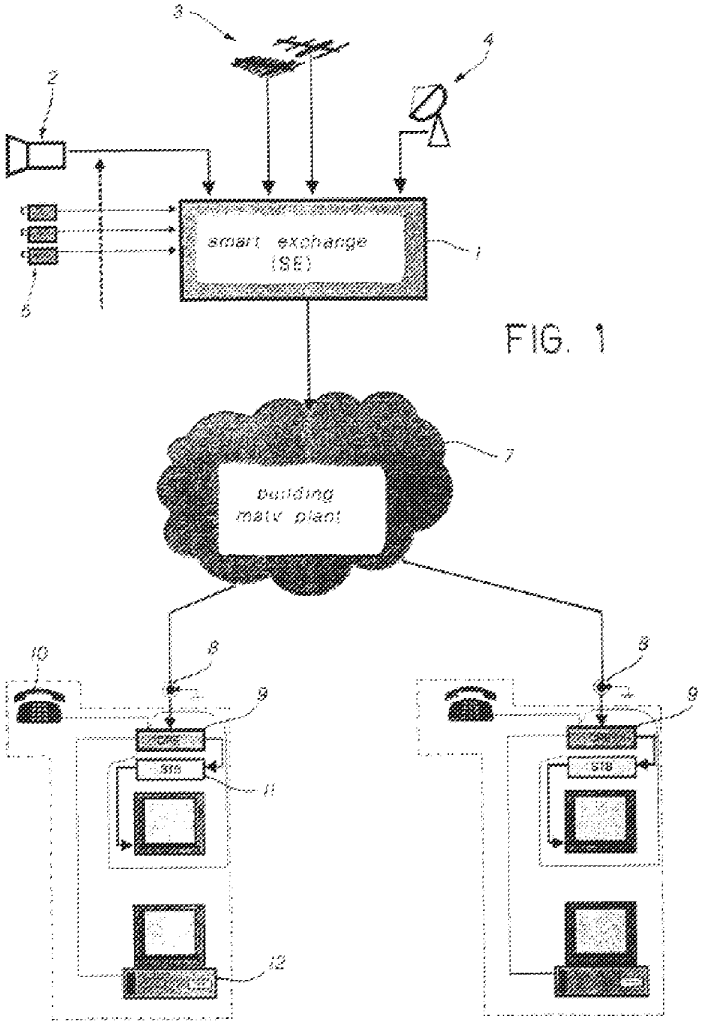
Asserted Claims	Williams '873
	indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '873 at Fig. 2:  FIG. 2 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.
42. The method of claim 14, wherein selecting and extracting comprises low-pass filtering the translated digitized broadband signal thereby	Williams '873 discloses, explicitly and/or inherently, wherein selecting and extracting comprises low-pass filtering the translated digitized broadband signal thereby substantially removing signal information from non-selected transponder channels.

Asserted Claims	Williams '873
substantially removing signal information from non-selected transponder channels.	*See* claim 14, *supra*. *See, e.g.*: Williams '873 at 2:15–25: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '873 at 5:59–6:11: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 9:40–48:

Asserted Claims	Williams '873
	The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix A thereto.

INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Ardemagni

WO 00/03542 ("Ardemagni") was filed on June 18, 1999 and published on January 20, 2000. Ardemagni therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(a) and/or (b). For the reasons listed below, Ardemagni invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.



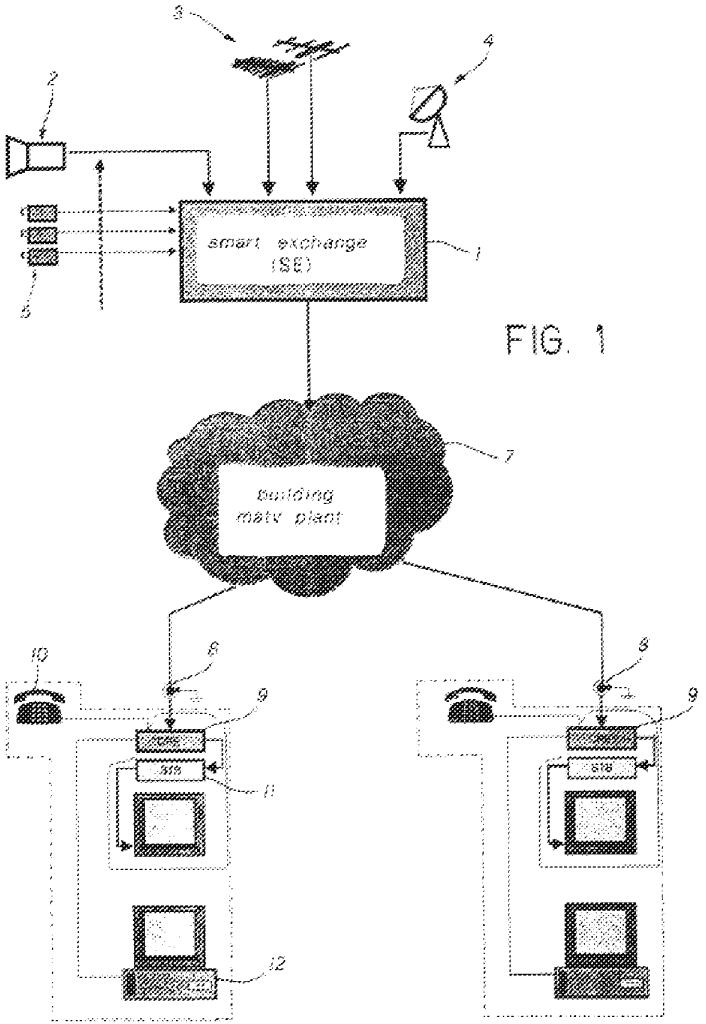
Asserted Claims	Ardemagni
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Ardemagni discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*: Ardemagni at Abstract:

[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.

Page 1761 of 4862

Asserted Claims	Ardemagni
	The invention relates to an optimized system for distribution of television and telecommunication services from a peripheral node to user terminals (10, 11, 12) comprising a bi-directional switch exchange (1) connected to said peripheral node, a facility (7) for bi-directional distribution of signals connected to said exchange (1) and at least one user apparatus (9) connected to said user terminals (10, 11, 12), said exchange (1) receiving from said peripheral node the signals belonging to said television and telecommunication services and from said bi-directional distribution facility (7) a local upstream data sequence including the television channel selection signals, said exchange (1) selecting some input signals belonging to television services and reallocating and/or frequency transmodulating them in order to transmit them, in combination with a local downstream data sequence, to said signal bi-directional distribution facility (7), said user apparatus (9) processing said local downstream data sequence and generating said local upstream data sequence to be transmitted to said exchange (1) together with the upstream data and/or voice channels related to said telecommunication services. Ardemagni at 3:5–11: It is an object of this invention, therefore, to enable in simple, economically convenient and reliable way to utilize a single plant for distributing the concerned signals, preferably a conventional, possibly already installed MATV plant, between the peripheral node and the user terminals connected thereto, for contemporaneous distribution of land based television channels as well as other television and/or telecommunication services, also including any interactive services. Ardemagni at 6:33–7:6: By referring now to Figure 1 , the system according to this invention comprises a bi-directional switch exchange 1 , positioned at a building node, which receives all signals belonging to the television and telecommunication services available in network HFC2, in system 3 which receives the land based television radio frequencies, in system 4 which receives the satellite based television radio frequencies as well as in local apparatuses 5 of

Asserted Claims	Ardemagni
	the building, such as, for instance, the Closed Circuit Television systems (CCTV) and the video intercommunication systems. Ardemagni at Fig. 1:



Asserted Claims	Ardemagni
	 FIG. 1

Asserted Claims	Ardemagni
	To the extent Ardemagni does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Ardemagni alone or it would have been obvious to combine Ardemagni with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[a] a gateway in communication with the ODU and at least one set top box (STB);	Ardemagni discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Ardemagni at 1:7–12: More particularly, this invention relates to a system of the above mentioned kind that enables the already existing facilities designed for centralized distribution of land based television channels, also known as Master Antenna TV (MATV) to also be adapted, in economically convenient and reliable way, to simultaneously distribute other television and telecommunication services, also including the interactive services. Ardemagni at 3:5–11: It is an object of this invention, therefore, to enable in simple, economically convenient and reliable way to utilize a single plant for distributing the concerned signals, preferably a conventional, possibly already installed MATV plant, between the peripheral node and the user terminals connected thereto, for contemporaneous distribution of land based television channels as well as other television and/or telecommunication services, also including any interactive services. Ardemagni at 5:26–28:

Asserted Claims	Ardemagni
	Further according to this invention, said signal bi-directional distribution facility is an apparatus for centralized distribution of land based television channels or a Master Antenna TV (MATV) facility. Ardemagni at 7:16–31: As it will be detailedly described hereinafter, the system according to this invention allows to utilize a MATV plant or facility for conveying in bi-directional way the signals of all television and telecommunication services to the input of said exchange, thereby supplying them to all active user terminals (10, 11 , 12), by means of a selection operation, advanced up to the level of said exchange 1 , among the specific non land based television channels as requested by active STB terminals 11. In particular, when a user selects a specific satellite or cable based television channel on his STB terminal 11 , the selection signal returns to the exchange 1 in order to redefine its switching pattern and to supply the concerned STB terminal 11 with only the selected television channel, rather than all available channels. When it is considered that STB terminal 11 could also receive signals belonging to more than one television services, it evidently appears that a reduction is obtained in terms of occupation of the band of the transmission channel interposed between the building node and the individual socket 8. Ardemagni at 8:1–9: In particular, aiming at making the system according to this invention compatible with the distribution of signals belonging to land based television channels to users not having connections with other television services and consequently are not provided with STB terminals 11 , according to the preferred embodiment of this invention, all these signals are conveyed by the MATV facility 7, thereby eliminating the signals replicated with the worst Signal-to-Noise Ratio (SNR) at the most, and maintaining the selection at a level corresponding to the user television set. Ardemagni at 8:26–35:

Asserted Claims	Ardemagni
	In this respect, the signals conveyed by said facility 7 from the exchange 1 to the various user apparatuses 9, by which the so-called "downstream" flow or channel is formed, comprise all signals belonging to land based television channels, coming from the receiver system 3 for the land based television radio frequencies, all signals belonging to downstream data and/or voice channels corresponding to telecommunication services, the signals belonging to satellite based and/or cable based television channels as selected by active user STB terminals 11 and lastly signals generated by exchange 1 for controlling said active STB terminals 11. Ardemagni at 16:12–21: It will also be apparent to those skilled in the art that a system according to this invention can easily be modified and/or adapted to process signals belonging to further television and/or telecommunication services. By way of exemplification, as it is shown in Figures 4 and 5, CCTV systems 5 can be provided such that, by suitable insertion of signals related to video and/or audio and/or control functions into channels upstream or downstream of said exchange 1 , they can be transmitted unaltered along said MATV facility 7 or they can be transmitted only if activated by the user and reallocated in frequency by said exchange 1. Ardemagni at 16:33–17:10: Said already existing or newly realized MATV facility 7 appears to be completely transparent to the usual broadcast or diffusion of land based television channels. In view of the above, exchange 1 is compatible with the usual services offered by said MATV facility 7 and any user not desiring to be connected to further television or telecommunication services continues anyway to utilize the land based signals. On the opposite side, any user desiring to be connected to further services should provide his own coaxial socket 8 (any one in his flat) with the concerned user apparatus 9, which acts as a "concentrator" in

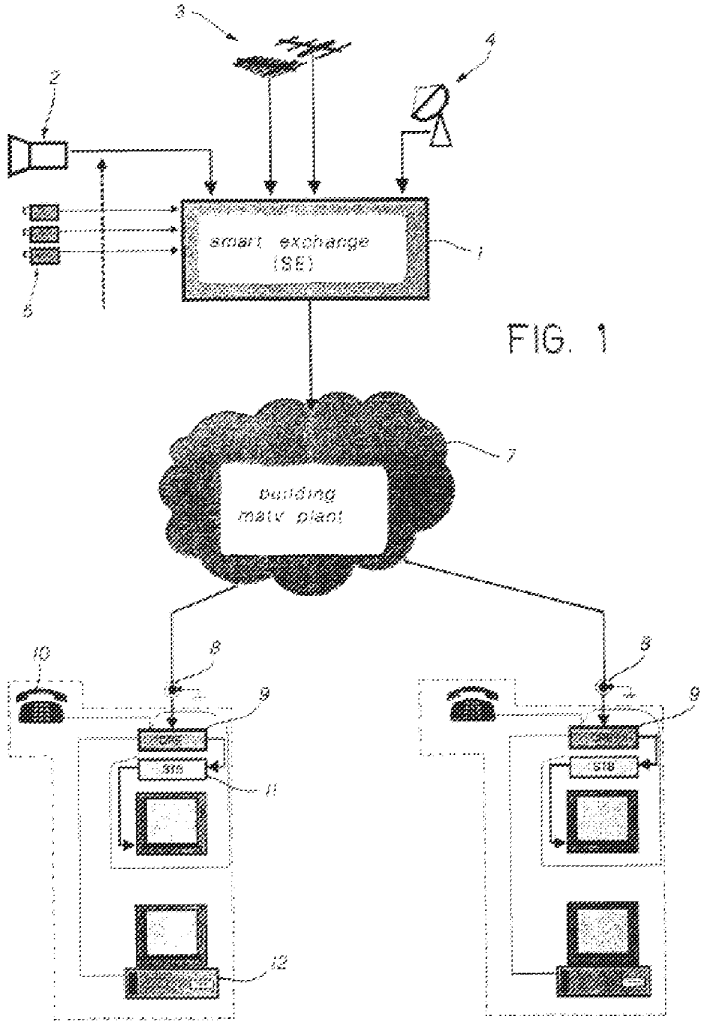
Asserted Claims	Ardemagni
	respect of the various user terminals (10, 11 , 12) installed in the concerned apartment. The connection between user apparatus 9 and said user terminals (10, 11 , 12) is realized by means of standard interface units (telephone cable, coaxial cable or infrared coupling), but it is possible to realize a radio connection, as well. Ardemagni at 17:18–23: The above exchange 1 is coupled, on one side, to the various input services outcoming from the antennas and/or from external cables, namely the land based television channels, the HFC telecommunication services, the satellite based television channels and, on the other side, namely the output side, to coaxial cable of said MATV distribution facility 7. Ardemagni at 17:29–18:2: Apparatus 9 performs the function to "dialogue" with said exchange 1 (in order to manage the MATV facility 7 in a suitable form to convey a plurality of interactive and not-interactive television services) and, at the same time, it is "open" to conveying telecommunication signals so that said MATV facility 7 can be effectively considered as a natural completion of radio based point-multipoint or PTM access systems presently studied, in order to easily apply such PTM systems in urban areas where the users are to a large extent distributed in buildings and apartments. Ardemagni at Fig. 1:

Asserted Claims	Ardemagni
	 FIG. 1

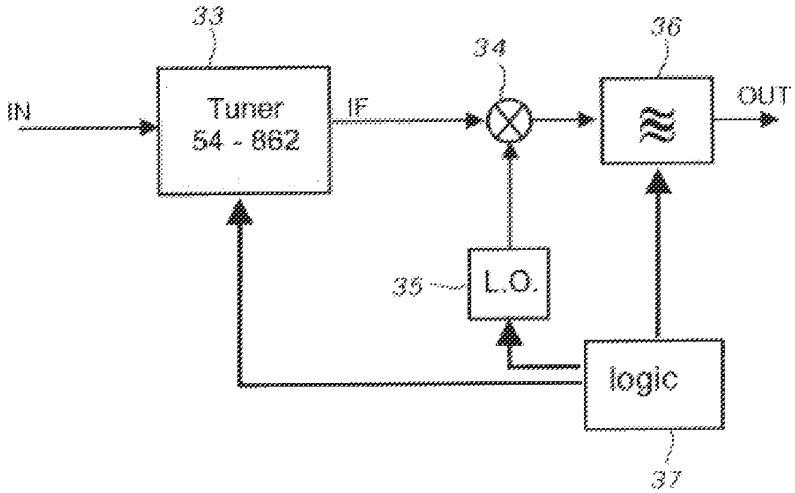
Asserted Claims	Ardemagni
	To the extent Ardemagni does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Ardemagni alone or it would have been obvious to combine Ardemagni with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information;	Ardemagni discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*: Ardemagni at Abstract: The invention relates to an optimized system for distribution of television and telecommunication services from a peripheral node to user terminals (10, 11, 12) comprising a bi-directional switch exchange (1) connected to said peripheral node, a facility (7) for bi-directional distribution of signals connected to said exchange (1) and at least one user apparatus (9) connected to said user terminals (10, 11, 12), said exchange (1) receiving from said peripheral node the signals belonging to said television and telecommunication services and from said bi-directional distribution facility (7) a local upstream data sequence including the television channel selection signals, said exchange (1) selecting some input signals belonging to television services and reallocating and/or frequency transmodulating them in order to transmit them, in combination with a local downstream data sequence, to said signal bi-directional distribution facility (7), said user apparatus (9) processing said local downstream data sequence and generating said local upstream data sequence to be transmitted to said exchange (1) together with the upstream data and/or voice channels related to said telecommunication services.

Asserted Claims	Ardemagni
	Ardemagni at 3:12–4:19: Specific subject matter of this invention is an optimized system for distribution of television and telecommunication services from a peripheral node to user terminals, said television services including land based radio frequency broadcast television channels, satellite based radio frequency broadcast television channels and HFC network or cable based broadcast television channels, each of said telecommunication services including a downstream data and/or voice channel and an upstream data and/or voice channel, said system also including a bi- directional switch exchange connected to said peripheral node, a facility for bi-directional distribution of signals connected to said exchange and at least a user apparatus connected to said bi-directional facility as well as to said user terminals, said exchange comprising a filter, a frequency filtering and translating unit, a logic control unit, a combiner and a selector, said combiner and selector being connected to said bidirectional distribution facility, the signals belonging to said land based television channels being applied to the input of said combiner, said filter receiving the signals belonging to said cable based television channels and to said downstream data and/or voice channels, said filter separating the signals belonging to said downstream data and/or voice channels from the signals belonging to said cable based television channels, said filter also reallocating the signals belonging to said downstream data and/or voice channels to pre-established frequencies and applying them to the input of said combiner, said filter also applying the signals belonging to said cable based television channels to said frequency filtering and translating unit, the signals belonging to said satellite based television channels being also applied to said frequency filtering and translating unit, said selector being connected to said bi-directional distribution facility in order to receive a local upstream data sequence therefrom and to apply it to said control logic unit and to receive the signals belonging to said upstream data and/or voice channels therefrom and to apply them to said peripheral node, said control logic unit generating the control signals to be applied to said frequency filtering and translating unit and a local downstream data sequence to be applied to the input of said combiner, said frequency filtering and translating unit selecting the input signals and frequency reallocating and/or translating them for applying them to the input of said combiner, said combiner mixing the input signals and applying them to said bi-directional distribution facility, said user apparatus

Asserted Claims	Ardemagni
	including a demodulator, a logic unit, a modulator and a combiner, said logic unit processing said local downstream data sequence outcoming from said demodulator, said modulator modulating a local upstream data sequence related to said user apparatus, said combiner mixing the signals belonging to said local upstream data sequence as well as the signals belonging to upstream data and /or voice channels related to said user apparatus and applying them to said bidirectional distribution facility. Ardemagni at 4:28–35: Further according to this invention, said frequency filtering and translating unit comprises a converter unit for conversion of HFC radio frequencies, a converter unit for conversion of satellite based radio frequencies as well as a switch unit, said converter units having N inputs and N outputs, said switch unit having 2*N inputs and N outputs, the homologous outputs of both said converter units being alternatively selected by said switch unit and transferred to said frequency filtering and translating unit. Ardemagni at 7:16–31: As it will be detailedly described hereinafter, the system according to this invention allows to utilize a MATV plant or facility for conveying in bi-directional way the signals of all television and telecommunication services to the input of said exchange, thereby supplying them to all active user terminals (10, 11, 12), by means of a selection operation, advanced up to the level of said exchange 1 , among the specific non land based television channels as requested by active STB terminals 11. In particular, when a user selects a specific satellite or cable based television channel on his STB terminal 11 , the selection signal returns to the exchange 1 in order to redefine its switching pattern and to supply the concerned STB terminal 11 with only the selected television channel, rather than all available channels. When it is considered that STB terminal 11 could also receive signals belonging to more than one television services, it evidently appears that a reduction is obtained in terms of occupation of the band of the transmission channel interposed between the building node and the individual socket 8.



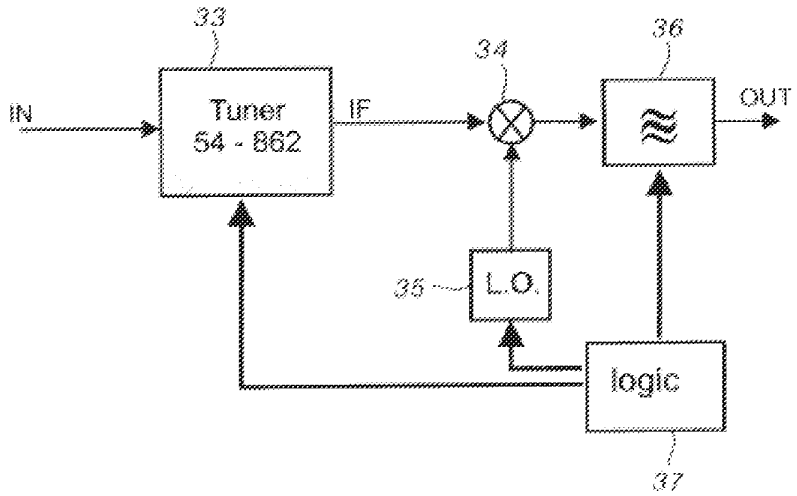
Asserted Claims	Ardemagni
	Ardemagni at 7:32–35: In other words, even if at least three television services are present at each user socket 8 and each service offers a big number of channels, each active user STB terminal 11 will select a single television channel. Ardemagni at 8:26–35: In this respect, the signals conveyed by said facility 7 from the exchange 1 to the various user apparatuses 9, by which the so-called "downstream" flow or channel i? formed, comprise all signals belonging to land based television channels, coming from the receiver system 3 for the land based television radio frequencies, all signals belonging to downstream data and/or voice channels corresponding to telecommunication services, the signals belonging to satellite based and/or cable based television channels as selected by active user STB terminals 11 and lastly signals generated by exchange 1 for controlling said active STB terminals 11. Ardemagni at 9:1–10: On the other hand, the signals conveyed by said facility 7 from the user apparatuses 9 to exchange 1 , by which the so-called "upstream" flow or channel is formed, comprise the signals belonging to upstream data and/or voice channels corresponding to telecommunication services as well as all signals corresponding to the selections performed by active user STB terminals 11. Such selection signals included in said upstream channel are utilized by said exchange 1 to convey at each time only signals belonging to satellite based and/or cable based television channels corresponding to the selections performed by the active user STB terminals 11. Ardemagni at 9:24–28:



Asserted Claims	Ardemagni
	Therefore, exchange 1 is adapted to allocate signals belonging to satellite based and/or cable based television channels into frequency band 16 variable in the range of 110 to 170 MHz and into frequency band 17 variable in the range of 230 to 470 MHz, as selected by active STB terminals 11. Ardemagni at 12:7–23: By referring to Figure 4a, each radio frequency filter-converter HFC is provided with a constant amplitude pass band and tuneable central frequency tuner 33, which filters the input HFC television signals, as allocated to frequency band extending between 54 and 862 MHz, and allows the HFC television signal selected by a STB terminal 11 to pass to the output. The output television signal is then frequency translated by means of a mixer 34 that mixes it with the signal of a selectable frequency local oscillator 35, as well as a band-pass filter 36, having a constant amplitude pass band and tuneable central frequency. In particular, a logic unit 37 generates the control signals to be used to establish the central frequency of tuner 33, the frequency of oscillator 35 and the central frequency of filter 36. Figure 4b illustrates a schematic diagram showing the frequency distribution of the signal modulated with 64QAM modulation (64 symbol Quadrature Amplitude Modulation) with a band width of 8 MHz, as appearing at the output of the converter-filter of Figure 4a when the frequency translation operation reallocates the selected television signal to band 17 (extended S band). Ardemagni at 12:24–13:10: By referring to Figure 5a, a first embodiment of the satellite radio frequency converter-filters includes a tuner 38, having a pass band of constant amplitude and tuneable central frequency, which filters the input satellite based television signals, as allocated to the frequency band extending from 950 and 2050 MHz, and allows the satellite based television signal selected by STB terminal 11 to pass to the output. In particular, the input satellite based television signals are modulated with Quaternary Phase Shift Keying (QPSK) modulation with a band width of

Asserted Claims	Ardemagni
	40 MHz. The television signal outputted by tuner 38 is then frequency translated by means of mixer 39 that mixes it with the signal of a selectable frequency local oscillator 40, as well as a band-pass filter 41, having a constant amplitude pass band and tuneable central frequency. In particular, a logic unit 42 generates the control signals to be used to establish the central frequency of tuner 38, the frequency of oscillator 40 and the central frequency of filter 41. In this case, channel QPSK appears to be reallocated, for instance to band 17, but it still occupies a band of 40 MHz. This means that the satellite radio frequency converter-filter of Figure 5a has a simple and low cost construction, but it still entails a band occupation 5 times larger than the band occupied by a 64QAM modulated signal, thereby reducing the number N of television channels allocable to facility 7. Furthermore, since the QPSK modulation is not compatible with STB terminals 11 for HFC television channels, an additional STB terminal 43 is anyway needed downstream of socket 8 in order to perform the transmodulation from QPSK to 64QAM system. Ardemagni at 13:21–37: As it is shown in Figure 3, each one of said N pairs of homologous outputs of the radio frequency conversion units 31 and 32, respectively, is coupled to one of N switches 46 that form a N output switching unit 47. In particular, each switch 46 corresponds to a STB terminal 11. Obviously, a HFC or satellite based television signal is present at the output of each switch 46, according to the selection of the corresponding STB terminal 11. Anyway, it is also possible to implement the arrangement so that, when the terminals connected at a given time are M, where M < N, the outputs of (N - M) switches 46 are in a high impedance condition. The N outputs (or the M active outputs) of said switching unit 47 are added in combiner 48 to the signals on the VHF output 19 and on the UHF output 20 of said filter unit 18 and to the signals belonging to the downstream data and/or voice channels of the telecommunication services available on output 23 of said filter 22. The output of combiner 48 forms the downstream channel that is conveyed from the exchange 1 through a duplexer 49 as well as the MATV facility 7 to the sockets 8 and to the user apparatuses 9.

Asserted Claims	Ardemagni
	Ardemagni 14:1–10: Upstream channel that is conveyed from said user apparatuses 9 to exchange 1 through said MATV facility 7 is transmitted by duplexer 49 to a selector 50 of local data. Said upstream channel is preferably allocated to frequency band extending from 5 to 30 MHz. Selector 50 separates all those signal corresponding to television channel selections performed by active STB terminals 11 , which form a local upstream data sequence, from signals belonging to upstream data and/or voice channel corresponding to telecommunication services. The signals belonging to upstream data and /or voice channels of telecommunication services are then passed unaltered and are transmitted to said HFC network 2. Ardemagni at 15:18–37: The data and/or voice upstream channels corresponding to telecommunication services outcoming from said telephone set 10, from said STB terminal 11 and from said PC 12 are modulated by a TELCO modulator 65 for telecommunication services. The signal travelling on an IR carrier outcoming from a remote controller 66 for selection of the television program and control of said STB terminal 11 is received by a receiver 67 and sent to a FSK modulator 68 that generates the local upstream data sequence related to the STB terminal 11 connected to the concerned user apparatus 9. The signals outcoming from said TELCO modulator 65 and from said FSK modulator 69 are added together in a combiner unit 69 and relayed to a further modulator 70. Modulator 70 in combination with a local oscillator 71 tuned on the frequency allotted to the specific concerned STB terminal 11 generates the upstream channel related to the considered user apparatus 9 and conveys it through a band pass filter 72 to the MATV facility 7 to enable it to reach the exchange 1. Preferably, the frequency on which said local oscillator 71 is tuned is comprised in the frequency band which extends from 5 to 30 MHz and coincides with the pass band of said filter 72. In particular, said local oscillator 71 can also transmit the signal for acknowledging the address of said STB terminal 11 to logic unit 60.



Asserted Claims	Ardemagni
	Ardemagni at 16:1–5: In this way, the selection performed by a user is routed to the exchange 1 rather than directly to said STB terminal 1 , through said upstream channel by means of a combination of it with the TELCO data on a local oscillator of a frequency in the band of 5 to 30 MHz allotted to any individual user. Ardemagni 17:11–17: Also the simple selection performed by the user of a desired (not land based) television channel in respect of any one of the various available services is "intercepted" and routed through the upstream flow to said exchange 1 where it is compared with other analogous selections and consequently managed. In this case, a local (building) data channel is involved which is possibly a portion of an upstream data flow of greater amplitude. Ardemagni at Fig. 1:

9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Ardemagni discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*:

Asserted Claims	Ardemagni
	Ardemagni at 5:22–25: Still according to this invention, said satellite based radio frequency converter unit comprises N converter-filters, each of which comprises a transmodulator and a control logic unit, said transmodulator filtering , transmodulating and frequency translating the input signal. Ardemagni at 12:7–23: By referring to Figure 4a, each radio frequency filter-converter HFC is provided with a constant amplitude pass band and tuneable central frequency tuner 33, which filters the input HFC television signals, as allocated to frequency band extending between 54 and 862 MHz, and allows the HFC television signal selected by a STB terminal 11 to pass to the output. The output television signal is then frequency translated by means of a mixer 34 that mixes it with the signal of a selectable frequency local oscillator 35, as well as a band-pass filter 36, having a constant amplitude pass band and tuneable central frequency. In particular, a logic unit 37 generates the control signals to be used to establish the central frequency of tuner 33, the frequency of oscillator 35 and the central frequency of filter 36. Figure 4b illustrates a schematic diagram showing the frequency distribution of the signal modulated with 64QAM modulation (64 symbol Quadrature Amplitude Modulation) with a band width of 8 MHz, as appearing at the output of the converter-filter of Figure 4a when the frequency translation operation reallocates the selected television signal to band 17 (extended S band). Ardemagni at 12:24–13:10: By referring to Figure 5a, a first embodiment of the satellite radio frequency converter-filters includes a tuner 38, having a pass band of constant amplitude and tuneable central frequency, which filters the input satellite based television signals, as allocated to the frequency band extending from 950 and 2050 MHz, and allows the satellite based

Asserted Claims	Ardemagni
	television signal selected by STB terminal 11 to pass to the output. In particular, the input satellite based television signals are modulated with Quaternary Phase Shift Keying (QPSK) modulation with a band width of 40 MHz. The television signal outputted by tuner 38 is then frequency translated by means of mixer 39 that mixes it with the signal of a selectable frequency local oscillator 40, as well as a band-pass filter 41, having a constant amplitude pass band and tuneable central frequency. In particular, a logic unit 42 generates the control signals to be used to establish the central frequency of tuner 38, the frequency of oscillator 40 and the central frequency of filter 41. In this case, channel QPSK appears to be reallocated, for instance to band 17, but it still occupies a band of 40 MHz. This means that the satellite radio frequency converter-filter of Figure 5a has a simple and low cost construction, but it still entails a band occupation 5 times larger than the band occupied by a 64QAM modulated signal, thereby reducing the number N of television channels allocable to facility 7. Furthermore, since the QPSK modulation is not compatible with STB terminals 11 for HFC television channels, an additional STB terminal 43 is anyway needed downstream of socket 8 in order to perform the transmodulation from QPSK to 64QAM system. Ardemagni 14:11–25: The above mentioned local upstream data sequence, after demodulation by demodulator 5, is conveyed through an input/output (I/O) interface to a logic control unit 54 aimed at controlling said exchange 1 , which, by decoding them, provides for reading the address of the caller unit (identification of the STB terminal 11 formulating the request) as well as for construing the request. Based upon the requests, said logic unit 54 generates (if necessary) the control signals controlling said filtering and frequency translating unit 30 as well as the local downstream data sequence for controlling said STB terminal 11. Such local downstream data sequence, through said interface unit 53 and a modulator 55, preferably a binary frequency variation modulator (FSK = Frequency Shifting Keying), is coupled to the input of combiner 48 in order to be added to other signals by which the downstream channel of said exchange 1 is formed. Preferably, the carrier of said local downstream data sequence is at a frequency of 40 MHz.

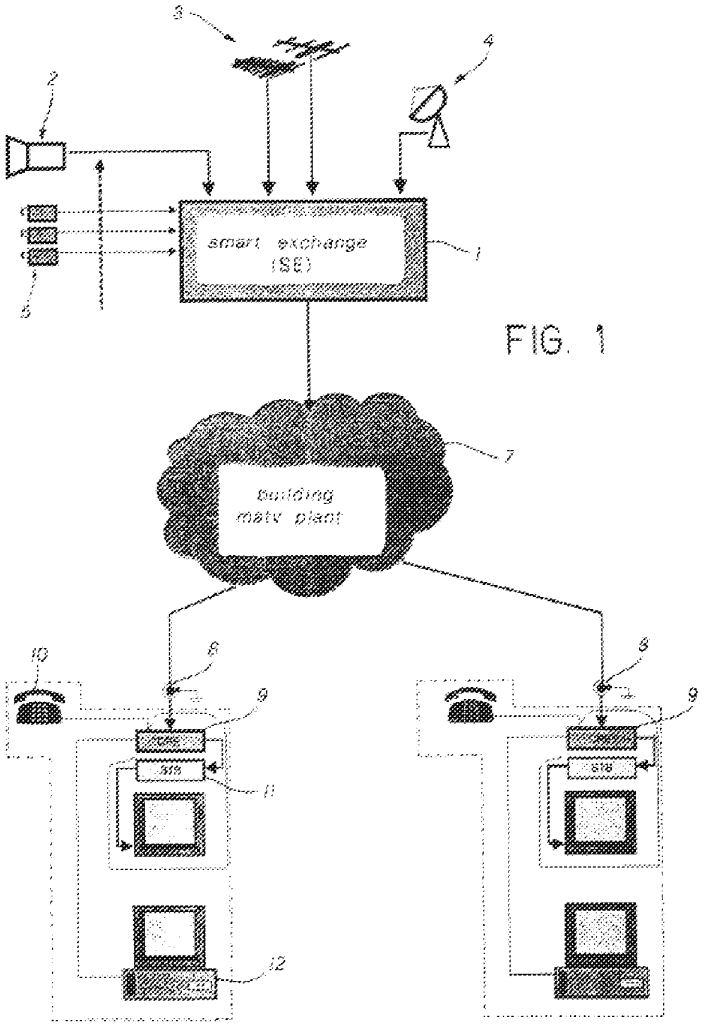
9[d] a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal;	Ardemagni discloses, explicitly and/or inherently, a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal. *See, e.g.*: Ardemagni at Abstract:

Asserted Claims	Ardemagni
	The invention relates to an optimized system for distribution of television and telecommunication services from a peripheral node to user terminals (10, 11, 12) comprising a bi-directional switch exchange (1) connected to said peripheral node, a facility (7) for bi-directional distribution of signals connected to said exchange (1) and at least one user apparatus (9) connected to said user terminals (10, 11, 12), said exchange (1) receiving from said peripheral node the signals belonging to said television and telecommunication services and from said bi-directional distribution facility (7) a local upstream data sequence including the television channel selection signals, said exchange (1) selecting some input signals belonging to television services and reallocating and/or frequency transmodulating them in order to transmit them, in combination with a local downstream data sequence, to said signal bi-directional distribution facility (7), said user apparatus (9) processing said local downstream data sequence and generating said local upstream data sequence to be transmitted to said exchange (1) together with the upstream data and/or voice channels related to said telecommunication services. Ardemagni at 3:12–4:19: Specific subject matter of this invention is an optimized system for distribution of television and telecommunication services from a peripheral node to user terminals, said television services including land based radio frequency broadcast television channels, satellite based radio frequency broadcast television channels and HFC network or cable based broadcast television channels, each of said telecommunication services including a downstream data and/or voice channel and an upstream data and/or voice channel, said system also including a bi- directional switch exchange connected to said peripheral node, a facility for bi-directional distribution of signals connected to said exchange and at least a user apparatus connected to said bi-directional facility as well as to said user terminals, said exchange comprising a filter, a frequency filtering and translating unit, a logic control unit, a combiner and a selector, said combiner and selector being connected to said bidirectional distribution facility, the signals belonging to said land based television channels being applied to the input of said combiner, said filter receiving the signals belonging to said cable based television channels and to said downstream data and/or voice channels, said filter separating the signals belonging to said downstream data and/or voice

Asserted Claims	Ardemagni
	channels from the signals belonging to said cable based television channels, said filter also reallocating the signals belonging to said downstream data and/or voice channels to pre-established frequencies and applying them to the input of said combiner, said filter also applying the signals belonging to said cable based television channels to said frequency filtering and translating unit, the signals belonging to said satellite based television channels being also applied to said frequency filtering and translating unit, said selector being connected to said bi-directional distribution facility in order to receive a local upstream data sequence therefrom and to apply it to said control logic unit and to receive the signals belonging to said upstream data and/or voice channels therefrom and to apply them to said peripheral node, said control logic unit generating the control signals to be applied to said frequency filtering and translating unit and a local downstream data sequence to be applied to the input of said combiner, said frequency filtering and translating unit selecting the input signals and frequency reallocating and/or translating them for applying them to the input of said combiner, said combiner mixing the input signals and applying them to said bi-directional distribution facility, said user apparatus including a demodulator, a logic unit, a modulator and a combiner, said logic unit processing said local downstream data sequence outcoming from said demodulator, said modulator modulating a local upstream data sequence related to said user apparatus, said combiner mixing the signals belonging to said local upstream data sequence as well as the signals belonging to upstream data and /or voice channels related to said user apparatus and applying them to said bidirectional distribution facility. Ardemagni at 4:20–23: According to this invention, said exchange further comprises, upstream of said combiner, a unit for filtering the signals belonging to said land based television channels, which eliminates all replicated signals having the worst signal-to-noise ratio (SNR). Ardemagni at 4:24–27:

Asserted Claims	Ardemagni
	Still according to this invention, said television services further comprise television channels related to closed circuit television systems (CCTV) that are coupled to the input of said combiner or to said frequency filtering and translating unit. Ardemagni at 5:34–6:9: Still according to this invention, the local upstream or local downstream data sequences are modulated by digital modulation, preferably FSK and/or a PSK and/or QAM modulation and said user apparatus further comprises a digital demodulator arranged upstream of said logic unit, a frequency multiplexer and a TELCO demodulator for telecommunication services, arranged upstream of said user terminals, a TELCO modulator for telecommunication services, arranged downstream of said user terminals, a digital modulator which receives the television channel selection data from at least one user terminal as well as a combiner arranged downstream of said TELCO modulator and of said digital modulator and upstream of said bi-directional distribution facility. Ardemagni at 13:21–37: As it is shown in Figure 3, each one of said N pairs of homologous outputs of the radio frequency conversion units 31 and 32, respectively, is coupled to one of N switches 46 that form a N output switching unit 47. In particular, each switch 46 corresponds to a STB terminal 11. Obviously, a HFC or satellite based television signal is present at the output of each switch 46, according to the selection of the corresponding STB terminal 11. Anyway, it is also possible to implement the arrangement so that, when the terminals connected at a given time are M, where M < N, the outputs of (N - M) switches 46 are in a high impedance condition. The N outputs (or the M active outputs) of said switching unit 47 are added in combiner 48 to the signals on the VHF output 19 and on the UHF output 20 of said filter unit 18 and to the signals belonging to the downstream data and/or voice channels of the telecommunication services available on output 23 of said filter 22. The output of combiner 48 forms the downstream channel that is conveyed from the exchange

Asserted Claims	Ardemagni
	1 through a duplexer 49 as well as the MATV facility 7 to the sockets 8 and to the user apparatuses 9. Ardemagni at 15:18–37: The data and/or voice upstream channels corresponding to telecommunication services outcoming from said telephone set 10, from said STB terminal 11 and from said PC 12 are modulated by a TELCO modulator 65 for telecommunication services. The signal travelling on an IR carrier outcoming from a remote controller 66 for selection of the television program and control of said STB terminal 11 is received by a receiver 67 and sent to a FSK modulator 68 that generates the local upstream data sequence related to the STB terminal 11 connected to the concerned user apparatus 9. The signals outcoming from said TELCO modulator 65 and from said FSK modulator 69 are added together in a combiner unit 69 and relayed to a further modulator 70. Modulator 70 in combination with a local oscillator 71 tuned on the frequency allotted to the specific concerned STB terminal 11 generates the upstream channel related to the considered user apparatus 9 and conveys it through a band pass filter 72 to the MATV facility 7 to enable it to reach the exchange 1. Preferably, the frequency on which said local oscillator 71 is tuned is comprised in the frequency band which extends from 5 to 30 MHz and coincides with the pass band of said filter 72. In particular, said local oscillator 71 can also transmit the signal for acknowledging the address of said STB terminal 11 to logic unit 60. Ardemagni at Fig. 3:



Asserted Claims	Ardemagni
	 FIG. 3 To the extent Ardemagni does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Ardemagni alone or it would have been obvious to combine Ardemagni with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[e] wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the	Ardemagni discloses, explicitly and/or inherently, wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs. *See, e.g.*:

Asserted Claims	Ardemagni
programs over a digital local area network (LAN) to STBs.	Ardemagni at 1:7–12: More particularly, this invention relates to a system of the above mentioned kind that enables the already existing facilities designed for centralized distribution of land based television channels, also known as Master Antenna TV (MATV) to also be adapted, in economically convenient and reliable way, to simultaneously distribute other television and telecommunication services, also including the interactive services. Ardemagni at 3:5–11: It is an object of this invention, therefore, to enable in simple, economically convenient and reliable way to utilize a single plant for distributing the concerned signals, preferably a conventional, possibly already installed MATV plant, between the peripheral node and the user terminals connected thereto, for contemporaneous distribution of land based television channels as well as other television and/or telecommunication services, also including any interactive services. Ardemagni at 5:26–28: Further according to this invention, said signal bi-directional distribution facility is an apparatus for centralized distribution of land based television channels or a Master Antenna TV (MATV) facility. Ardemagni at 7:16–31: As it will be detailedly described hereinafter, the system according to this invention allows to utilize a MATV plant or facility for conveying in bi-directional way the signals of all television and telecommunication services to the input of said exchange, thereby supplying them to all active user terminals (10, 11 , 12), by means of a selection operation, advanced up to the level of said exchange 1 , among the specific non land based television channels as requested by active STB terminals 11. In particular, when a user selects a specific satellite or cable based television channel on his STB terminal 11 , the selection signal

Asserted Claims	Ardemagni
	returns to the exchange 1 in order to redefine its switching pattern and to supply the concerned STB terminal 11 with only the selected television channel, rather than all available channels. When it is considered that STB terminal 11 could also receive signals belonging to more than one television services, it evidently appears that a reduction is obtained in terms of occupation of the band of the transmission channel interposed between the building node and the individual socket 8. Ardemagni at 8:1–9: In particular, aiming at making the system according to this invention compatible with the distribution of signals belonging to land based television channels to users not having connections with other television services and consequently are not provided with STB terminals 11 , according to the preferred embodiment of this invention, all these signals are conveyed by the MATV facility 7, thereby eliminating the signals replicated with the worst Signal-to-Noise Ratio (SNR) at the most, and maintaining the selection at a level corresponding to the user television set. Ardemagni at 8:26–35: In this respect, the signals conveyed by said facility 7 from the exchange 1 to the various user apparatuses 9, by which the so-called "downstream" flow or channel is formed, comprise all signals belonging to land based television channels, coming from the receiver system 3 for the land based television radio frequencies, all signals belonging to downstream data and/or voice channels corresponding to telecommunication services, the signals belonging to satellite based and/or cable based television channels as selected by active user STB terminals 11 and lastly signals generated by exchange 1 for controlling said active STB terminals 11. Ardemagni at 16:12–21:

Asserted Claims	Ardemagni
	It will also be apparent to those skilled in the art that a system according to this invention can easily be modified and/or adapted to process signals belonging to further television and/or telecommunication services. By way of exemplification, as it is shown in Figures 4 and 5, CCTV systems 5 can be provided such that, by suitable insertion of signals related to video and/or audio and/or control functions into channels upstream or downstream of said exchange 1 , they can be transmitted unaltered along said MATV facility 7 or they can be transmitted only if activated by the user and reallocated in frequency by said exchange 1. Ardemagni at 16:33–17:10: Said already existing or newly realized MATV facility 7 appears to be completely transparent to the usual broadcast or diffusion of land based television channels. In view of the above, exchange 1 is compatible with the usual services offered by said MATV facility 7 and any user not desiring to be connected to further television or telecommunication services continues anyway to utilize the land based signals. On the opposite side, any user desiring to be connected to further services should provide his own coaxial socket 8 (any one in his flat) with the concerned user apparatus 9, which acts as a "concentrator" in respect of the various user terminals (10, 11 , 12) installed in the concerned apartment. The connection between user apparatus 9 and said user terminals (10, 11 , 12) is realized by means of standard interface units (telephone cable, coaxial cable or infrared coupling), but it is possible to realize a radio connection, as well. Ardemagni at 17:18–23: The above exchange 1 is coupled, on one side, to the various input services outcoming from the antennas and/or from external cables, namely the land based television channels, the HFC telecommunication services, the satellite based television channels and, on the other side, namely the output side, to coaxial cable of said MATV distribution facility 7.

Asserted Claims	Ardemagni
	Ardemagni at 17:29–18:2: Apparatus 9 performs the function to "dialogue" with said exchange 1 (in order to manage the MATV facility 7 in a suitable form to convey a plurality of interactive and not-interactive television services) and, at the same time, it is "open" to conveying telecommunication signals so that said MATV facility 7 can be effectively considered as a natural completion of radio based point-multipoint or PTM access systems presently studied, in order to easily apply such PTM systems in urban areas where the users are to a large extent distributed in buildings and apartments. Ardemagni at Fig. 1:

Asserted Claims	Ardemagni
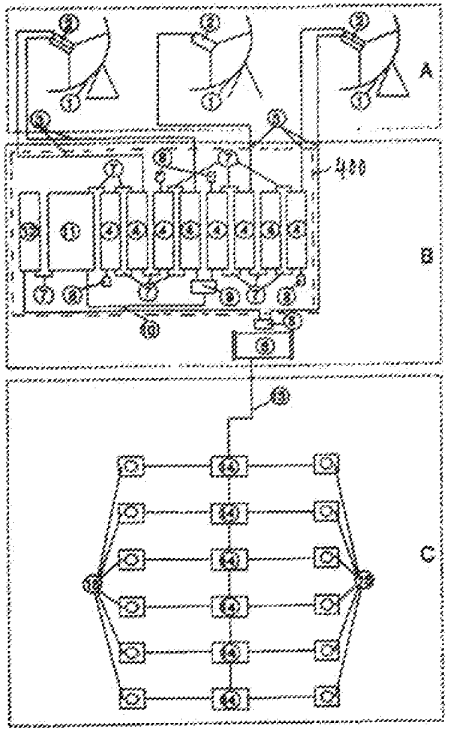
12. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network.	Ardemagni discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network. *See* claim 10, *supra*. To the extent Ardemagni does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Ardemagni alone or it would have been obvious to combine Ardemagni with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Exhibit B2 – Carnero Invalidity Claim Chart

INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Carnero



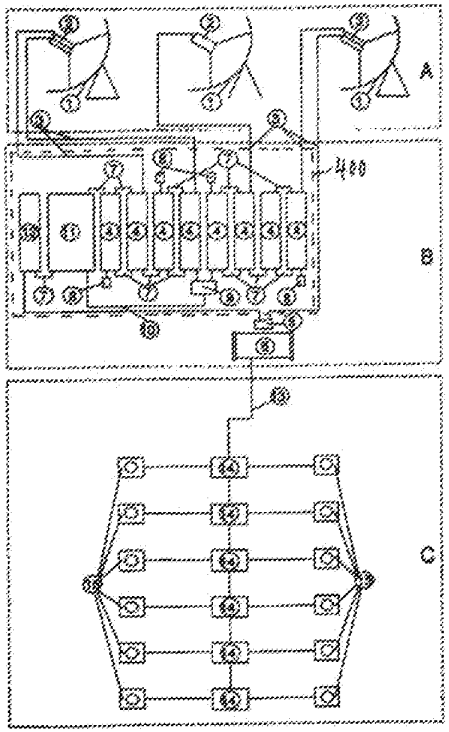
European Patent Application EP 0 740 434 ("Carnero") was published on October 30, 1996. Carnero therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(a) and/or (b). For the reasons listed below, Carnero invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Carnero
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Carnero discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*: Carnero at Abstract:

[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.

Exhibit B2 – Carnero Invalidity Claim Chart

Asserted Claims	Carnero
	(57) The invention relates to a system, in particular, a community antenna system, for distributing television signals of different channels. The system consists of a signal generator (A), a head device (B) with a signal processing unit (400) and a distribution network (C, 13). According to the invention, the signal processing device (400) comprises at least one channel-specific converter (4). Each channel-specific converter (4) converts a pre-definable channel in the intermediate frequency band, into another channel in the intermediate frequency band. Several channel-specific converters (4) are connected in a daisy chain. Channels that are not to be distributed are overlapped by channels that are to be transmitted through amplification of their signal levels. The processed signals originate from different polarities and/or different satellites and are transmitted to user outlets (15) via a single distribution cable (13). Carnero at Fig. 3:



Asserted Claims	Carnero
	 Carnero at 2:4-12: The present invention relates to a system for distributing signals, in particular, a community antenna system for distributing television signals of different channels, according to the generic concept of Claim 1. At present, two main systems are used for this purpose, which are shown schematically in Figures 1 and 2:

Asserted Claims	Carnero
	In the first state-of-the-art system, shown in Figure 1, signals received by the antenna are frequency-demodulated, individually for each channel, after amplification and conversion by units already known in the field (low-noise amplifier LNA, low-noise block converter LNB). Then, the channel-specific frequency-demodulated signals are amplitude-modulated in a conventional UHF television channel. Carnero at 3:9-17: The system, according to the invention, is characterized by a number of advantages. According to the invention, the user is provided with pre-definable channels, via only one distribution cable, which are individually selected from signals originating from one antenna or from several antennas. Individual selection of channels can be used to meet the demand of system users for the reception of predefined channels. The individual channel converters provided, according to the invention, which convert a pre-definable channel into another channel, as well as the system as a whole, are designed in a simple circuit. The channel-specific converters can be set to any frequency in a pre-definable frequency band. In this way, the system, according to the invention, makes it possible to flexibly meet a changed demand of the system users with regard to the reception of pre-definable channels. Carnero at page 4: The signal distribution system shown in the drawings, as well as in Figure 3, consists of three blocks A, B and C. Block A is a signal generator, block B is a head device with a signal processing unit and block C represents the distribution network. Blocks A, B and C are designed as follows: 1. Block A is a signal generator consisting of at least one antenna 1 and known down converters 2 (low-noise amplifier LNA, low-noise block converter LNB). The received signals may originate from different broadcast and/or telecommunications satellites and/or have different polarities (horizontal, vertical). The down-converters 2 convert the received signals, in an already known way, from the received frequency range of, for example, 11.7

Asserted Claims	Carnero
	- 12.5 GHz; 10.7 - 11.7 GHz; 12.5 - 12.75 GHz or preferably 10.7 - 12.5 GHz into an intermediate frequency range of, for example, 950 - 1760 MHz or preferably 950 MHz and 2,050 MHz. 2. Block B is a head device with a signal processing device 400, in which channel-specific converters 4 are arranged. The channel-specific converters 4 are described in more detail, in particular, with reference to Figure 7. Various designs of the signal processing device 400 are shown in Figures 3, 4, 5, and 6; 3. The distribution network C has a single distribution cable 13, through which the signals are transmitted to user outlets 15, via tapping or diverters 14. Carnero at 10:1-21: After the mixing process has been carried out in the second mixer 5, one or more channels shown in Figure 10 will be received, these channels then being distributed via the single distribution cable 13. In this case, as illustrated in Figure 10, channel 65 is superimposed on channel 60 (cf. larger amplitude of 65 compared to 60), channel 72 on channel 36, channel 68 on channel 44, channel 82 on channel 2, channel 77 on channel 6, channel 17 on channel 12, channel 89 on channel 18, and channel 41 on channel 24. Thus, according to the invention, it is provided that signals, in particular, television signals transmitted via satellites, of different channels are distributed in a community antenna system. The signals are received in a signal generator A, and the received signals of a certain polarity (H, V) are converted from a receive frequency band into signals in an intermediate frequency band. The signals converted to the intermediate frequency band are processed and the processed signals are transmitted to user outlets 15, via a single distribution cable 13, in the intermediate frequency band. In this process, individual predefinable channels in the intermediate frequency band are converted into other channels in the intermediate frequency band.

Asserted Claims	Carnero
	First channels converted in the intermediate frequency band are mixed with second channels in the intermediate frequency band, and the first and second channels are transmitted over the distribution cable 13. In particular, different signal levels are generated for two channels of the same frequency, converted to the intermediate frequency band, with the signal levels of the signals of different channels differing by at least 15 dB. Carnero at Claims 1-2: 1. A system for distributing signals, in particular, a community antenna system for distributing television signals of different channels transmitted, in particular, via satellites, said system comprising - A signal generator (A) comprising at least one antenna (1) receiving the signals and at least one down-converter, (LNA/LNB 2) converting received signals of a certain polarity (H, V) from a receive frequency band, into signals in an intermediate frequency band, - a head device (B), which is connected downstream of the signal generator (A), and which has at least one signal processing unit (400), which is connected on the input side via a cable (3) to the down converter (LNA/LNB 2), and which can be connected on the output side to a single distribution cable (13), via which the processed signals are transmitted in the intermediate frequency band to user outlets (15), characterized by the fact, that the signal processing unit (400) of the head device (B) has at least one channel-specific converter (4), and that the channel-specific converter (4) converts a pre-definable channel, in the intermediate frequency band, into another channel in the intermediate frequency band. 2. A system according to Claim 1, characterized in that channel-specific converters (4) of the head device (B) are integrated in at least one converter module (40), and that the converter module (40) can be connected at its input, via the cable (3), to the down converters (LNA/LNB 2), and at its output to the distribution cable (13).

Asserted Claims	Carnero
	To the extent Carnero does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Carnero alone or it would have been obvious to combine Carnero with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[a] a gateway in communication with the ODU and at least one set top box (STB);	Carnero discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Carnero at page 4: The signal distribution system shown in the drawings, as well as in Figure 3, consists of three blocks A, B and C. Block A is a signal generator, block B is a head device with a signal processing unit and block C represents the distribution network. Blocks A, B and C are designed as follows: 1. Block A is a signal generator consisting of at least one antenna 1 and known down converters 2 (low-noise amplifier LNA, low-noise block converter LNB). The received signals may originate from different broadcast and/or telecommunications satellites and/or have different polarities (horizontal, vertical). The down-converters 2 convert the received signals, in an already known way, from the received frequency range of, for example, 11.7 - 12.5 GHz; 10.7 - 11.7 GHz; 12.5 - 12.75 GHz or preferably 10.7 - 12.5 GHz into an intermediate frequency range of, for example, 950 - 1760 MHz or preferably 950 MHz and 2,050 MHz. 2. Block B is a head device with a signal processing device 400, in which channel-specific converters 4 are arranged. The channel-specific converters 4 are described in more detail, in particular, with reference to Figure 7. Various designs of the signal processing device 400 are shown in Figures 3, 4, 5, and 6;

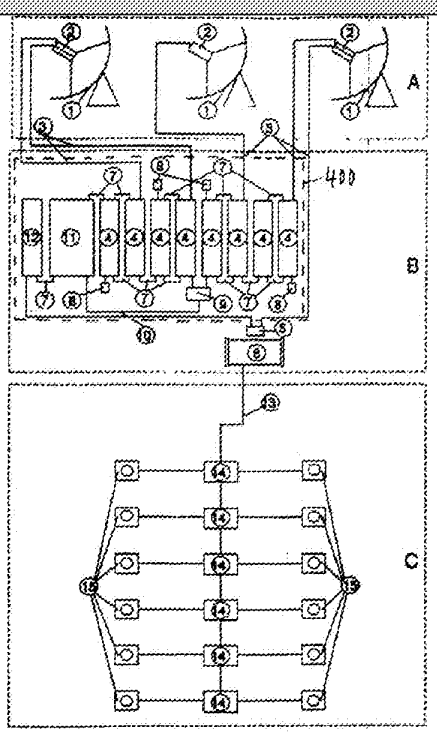
Asserted Claims	Carnero
	3. The distribution network C has a single distribution cable 13, through which the signals are transmitted to user outlets 15, via tapping or diverters 14. Carnero at Fig. 3:  To the extent Carnero does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Carnero alone or it would have been obvious to combine Carnero with one or more prior

Asserted Claims	Carnero
	art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information;	Carnero discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*: Carnero at 3:9-17: The system, according to the invention, is characterized by a number of advantages. According to the invention, the user is provided with pre-definable channels, via only one distribution cable, which are individually selected from signals originating from one antenna or from several antennas. Individual selection of channels can be used to meet the demand of system users for the reception of predefined channels. The individual channel converters provided, according to the invention, which convert a pre-definable channel into another channel, as well as the system as a whole, are designed in a simple circuit. The channel-specific converters can be set to any frequency in a pre-definable frequency band. In this way, the system, according to the invention, makes it possible to flexibly meet a changed demand of the system users with regard to the reception of pre-definable channels. Carnero at 3:48-53: The channel-specific converters may each have a microprocessor, that controls at least one oscillator. The microprocessor allows a converter-external input device to be detachably connected to the microprocessor and data to be input to the converter and the microprocessor, respectively, designating a predeterminable input channel frequency and a predeterminable output channel frequency. In this way, the channel-specific converters can be easily set to a pre-definable input frequency and a pre-definable output frequency, by

Asserted Claims	Carnero
	which the frequency conversion of a channel is determined. The converter-external input device can also be designed as a remote-controlled transmitter. Carnero at page 4: The signal distribution system shown in the drawings, as well as in Figure 3, consists of three blocks A, B and C. Block A is a signal generator, block B is a head device with a signal processing unit and block C represents the distribution network. Blocks A, B and C are designed as follows: 1. Block A is a signal generator consisting of at least one antenna 1 and known down converters 2 (low-noise amplifier LNA, low-noise block converter LNB). The received signals may originate from different broadcast and/or telecommunications satellites and/or have different polarities (horizontal, vertical). The down-converters 2 convert the received signals, in an already known way, from the received frequency range of, for example, 11.7 - 12.5 GHz; 10.7 - 11.7 GHz; 12.5 - 12.75 GHz or preferably 10.7 - 12.5 GHz into an intermediate frequency range of, for example, 950 - 1760 MHz or preferably 950 MHz and 2,050 MHz. 2. Block B is a head device with a signal processing device 400, in which channel-specific converters 4 are arranged. The channel-specific converters 4 are described in more detail, in particular, with reference to Figure 7. Various designs of the signal processing device 400 are shown in Figures 3, 4, 5, and 6; 3. The distribution network C has a single distribution cable 13, through which the signals are transmitted to user outlets 15, via tapping or diverters 14. Block A of the system according to the invention, i.e., the signal generator, as shown for example in Figure 3, consists of antennas 1, which receive signals from television channels transmitted via satellites. If the antennas are parabolic antennas, a down converter 2 is arranged at the focal point of each antenna 1, which converts the received signals, in an

Asserted Claims	Carnero
	already known manner, from the satellite television reception frequency range of, for example, 10.7 - 12.5 GHz into the intermediate frequency range between 950 MHz and 2,050 MHz (usually referred to as the "first intermediate frequency"). Such down converters 2 with an amplifier LNA and a channel block converter LNB, are known and available on the market. Each antenna 1 has one or two downconverters 2 (or one downconverter with two outputs), depending on whether signals of one or two polarities (horizontal, vertical) are to be received per antenna. If the antenna 1 receives signals of one polarity, one down converter 2 is provided; if the antenna 1 receives signals of two polarities, two down converters 2 are provided. The down converters 2 are each connected to a cable 3 on the output side. In various design versions of the invention, one or more cables 3, as shown in Figures 3, 4, 5, 6, and 9, run to the signal processing unit 400 having at least one channel-specific converter 4. It may also be intended, that one or more cables 3, as shown in Figures 3, 6 and 9, run to a ("second") mixer 5, which is connected downstream to a channel-specific converter 4, or to a converter module 40 having at least one channel-specific converter 4. The channel-specific converters 4 of the head device B are preferably integrated in at least one converter module 40, wherein the converter module 40 can be connected at its input, via a cable 3, to a down converter (LNA/LNB) 2, and at its output to the distribution cable 13 (coaxial cable). Preferably, the distribution cable 13 is connected to the output of an amplifier 6, which may be connected downstream of the ("second") mixer 5. Carnero at 5:1-47: Each individual channel converter 4, the circuitry of which will be explained in detail in Figure 7, has two inputs and two outputs. As shown in Figures 3, 4, 5, 6 and 9, the channel-specific converters 4 of a converter module 40 are interconnected, in such a way, that an input (e.g., EC1 in Figure 7) of a first

Asserted Claims	Carnero
	converter module is connected to the input (e.g., EC2) of a second converter module (not shown in Figure 7), adjacent to the first converter module. Likewise, an output (such as SCI) of the first converter module is connected to the output (such as SC2) of the second converter module (daisy chain). This daisy-chain structure has the practical advantage, that not every individual channel converter 4 has to be connected to a down converter 2 via a separate cable 3, and that, furthermore, not every individual channel converter 4 has to be connected via a separate cable to a ("second") mixer (5), which is connected upstream of the distribution cable 13. It may be provided that each of the two inputs is respectively connected, e.g., via a respective known connecting bridge 7, to an input of an upstream channel-specific converter 4, or to the input of a downstream channel-specific converter 4. Likewise, with regard to the outputs, it can be provided that each of the two outputs is connected, for example, via a respective known connecting bridge 7, to an output of an upstream channel-specific converter 4 or to the output of a downstream channel-specific converter 4. Ideally, an identical housing is provided for each individual channel converter 4, i.e., a housing of the same spatial dimensions on which the input and output connections are arranged at the same locations. This allows the use of identical connecting bridges 7, each of which is used to establish an electrical connection either between two inputs or between two outputs. Furthermore, it may be provided that one input of a converter 4 (first converter 4 of a converter module 40, which is drawn on the right side of a converter module in figures 4 and 5, respectively) is connected to a cable 3, which transmits the signals generated by the down converters 2, or converted to the intermediate frequency range. One input of a converter 4 (last converter 4 of a converter module 40, which is drawn on the left in Figures 4 and 5) is connected to a supply source 11, which supplies the converters 4 and an amplifier 12 provided per signal processing unit 400. These channel-specific converters 4 receive on the input side the signals or channels in the intermediate frequency range, emitted by the down converters 2 and transmitted via the



Asserted Claims	Carnero
	cables 3, and convert the signals or channels in the intermediate frequency range, as will still be described based on Figures 9 and 10. Inputs of the channel-specific converters 4, which are not connected to the input of an adjacent converter or to which no cable 3 is connected, can be terminated with an ohmic resistor 8 of 75 ohms (cf. Figure 3, block B, reference number 8 above the converters 4; right converter module 40 in Figure 5; Figure 9, reference number 8 above the converters 4). Likewise, outputs of the channel-specific converters 4 can be terminated with an ohmic resistor 8 of 75 ohms (cf. Figure 3, block B, reference number 8 below the converters 4; right and left converter module 40 in Figure 5; Figures 6 and 9, reference number 8 below the converters 4). These are, in particular, the output of a first converter 4 (with respect to the signal flow) in a first converter module (right converter module in Figure 5), as well as the output of a last converter 4 (with respect to the signal flow) in a last converter module (left converter module in Figure 5). With each channel-specific converter 4, a channel is selected and converted from an input frequency, in the intermediate frequency range, to a predeterminable output frequency in the intermediate frequency range. As described earlier, multiple channel-specific converters 4, at least two, preferably four converters 4 may be integrated into a converter module 40. Two adjacent modules can be combined via a ("first") mixer 9. The output of the first mixer 9 is introduced into the feed source 11 and amplifier 12 arrangement by means of a connecting cable 10. The amplified signal is fed to the second mixer 5. The channel-specific converter 4 is preferably designed as follows: Carnero at 7:20-8:25:

Asserted Claims	Carnero
	As shown in Figure 3, the distribution network C consists of a single distribution cable 13, on which all channels, that are FM modulated, are transmitted. The distribution cable 13 is made up of a coaxial cable and runs to diverters 14, which output the signal to various user outlets 15. Figure 4 shows a signal processing unit 400 with one converter module 400 consisting of four channel-specific converters 4, while Figure 5 shows a signal processing unit 400 with two converter modules 400, each consisting of four channel-specific converters 4. In the system, according to the invention, the number of channel-specific converters 4 is equal to the number of channels coupled into the distribution cable 13, and transmitted to the user outlets 15, via the diverters 14. The channel-specific converters can be set to predeterminable input frequencies in the intermediate frequency range, and to predeterminable output frequencies in the intermediate frequency range. Figure 7 shows an example of a channel-specific converter 4. Two inputs EC1 and EC2 are electrically connected to each other and to an amplifier 42 via a directional coupler 41. The inputs EC1 and EC2 are mechanically designed, in such a way, that known connecting bridges (7 in Figure 4) can be used for connection to one input each of an adjacent channel-specific converter. In this way, several channel-specific converters can be integrated into one converter module. This type of connection thus consists in each of the two inputs EC1, EC2 being connected, e.g., via a respective known connection bridge, to an input of an upstream channel-specific converter 4 or to the input of a downstream channel-specific converter 4. Similarly, each of the two outputs SC1, SC2 of the converter 4 is respectively connected, for example, via a respective known connecting bridge, to an output of an upstream channel-specific converter 4 or to the output of a downstream channel-specific converter 4. This type of connection has the advantage of not requiring distributors, which would otherwise have to be connected downstream of the down converters 2, and connecting cables between these distributors and channel-specific converters.

Asserted Claims	Carnero
	The amplifier 42 amplifies the supplied signals, for example, in the frequency band from 950 to 2,050 MHz. The signals are fed to a tracking filter 43 on the input side. This filter is a bandpass filter tuned to the selected input channel frequency by means of a voltage, generated by a phase-locked loop (PLL) circuit 46. The circuit 46 is controlled by a microprocessor (MP) 49. A mixer 44 connected downstream of the tracking filter 43 is actuated by a local oscillator (OL) 45, which in turn is actuated by the PLL circuit 46. The mixer 44 converts the frequency of the selected channel present at inputs EC1 and EC2 to a frequency of 479.5 MHz. The signal formed by the mixer 44 is fed to a low-pass filter 47, whose cutoff frequency is 600 MHz, for example. This eliminates the signal from the local oscillator 45 and any unwanted signals formed during the mixing process. The signal is then filtered by means of a SAW 50 surface acoustic wave filter, which has, for example, a bandwidth of 27 MHz at a center frequency of 479.5 MHz. The amplifiers 48 and 51, which are connected upstream and downstream of the SAW (surface acoustic wave) filter, respectively, increase the signal level, in such a way, that the losses caused by the SAW filter 50 are compensated. The mixer 52 connected downstream of the amplifier 51 mixes the signal of the frequency 479.5 MHz, selected at the input, with a signal formed by a local oscillator (OL) 53. The local oscillator is controlled by a PLL circuit 54. The PLL circuit 54 is also controlled by the microprocessor 49. A tracking filter 55 is connected downstream of the mixer 52, which, like the filter 43, is a bandpass filter. The filter 55 eliminates the unwanted signals formed during the mixing done by the mixer 52. The output of filter 55 then carries the signal of the frequency-converted channel, which is fed to an amplifier 56.

Asserted Claims	Carnero
	The gain of amplifier 56 is controllable, so that the levels of the frequency-converted channel signal can be set to pre-definable values (cf., for example, channels 1 and 5 in Figure 8) A downstream directional coupler 57 feeds the amplified signal to the outputs SC1, SC2. The outputs SC1 and SC2 are mechanically designed, in such a way, that known connecting bridges (7 in Figure 4) can be used for connecting to one output each of an adjacent channel-specific converter. As shown in Figure 7, the converters 4 may include a microprocessor 49, that controls the PLL circuits 46 and 54 and determines the input and output frequency of the channel signal of the converters 4. Further, the microprocessor 49 may control the amplifier 56. An input unit 16 can be connected to the microprocessor 49, for example, via a 4-cable bus, through which the data of a pre-definable input and output frequency and/or control data for the amplifier 56 (signal amplification parameters) can be input into the microprocessor 49. The input unit 16 can have a control unit 162 (in particular, a microprocessor MP). A program assigned to the control unit 162 generates data as a function, for example, of the cutoff frequencies of the respective intermediate frequency range (950 MHz, 2,050 MHz), of channel bandwidths and channel spacings and signal levels of the channel signals, which corresponds to predefined technical specifications, and which is input into the microprocessor 49 of the channel-specific converter 4. The input unit 16 includes a keyboard 161, the control unit 162 and a display 163. The display shows data entered into the keypad 161, operator guidance information, and information indicating the state of the converter after it is configured by the data entered. The input unit 16 may be designed as a remote-controlled transmitter with a transmitting device, that transmits the data to be input to a receiver connected to the microprocessor 49 of the channel-specific converter. Asserted Claims	Carnero
	 Fig. 7 Carnero at 9:36-10:6: As shown in Figure 10, channels 70, 72, ...92, are located at circuit point g, channels 71, 73, ...93 are located at circuit point h, channels 65 - 69 are located at circuit point i, channels 49, 51...63, 33...47, 1, 3, ...31 are located at circuit point j, and channels 50, 52 ... 64; 34, 36, ... 48; 2, 4 ... 32 at circuit point k. The desired channels are selected from all available channels at the switching points d - k. For example, channels 60, 36, 44, 2, 6, 12, 18, and 24 available at circuit point k are not processed further, while channels 65, 72, 68, 82, 77, 17, 89, and 41 available at circuit points g, h, i, j, are further processed instead.

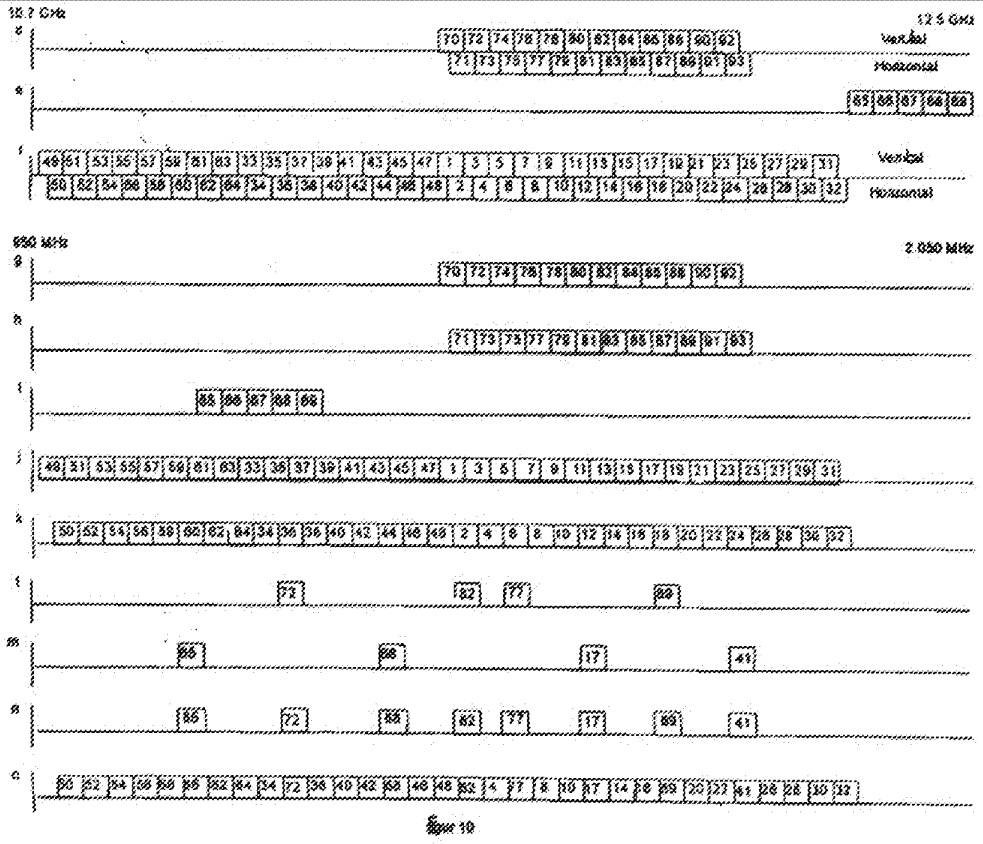
Asserted Claims	Carnero
	For this purpose, converter modules 40 are provided at the circuit points g, h, i, j, and the channel-specific converters 4 of the modules 40 are set to the input frequencies of each of the selected channels, and to the output frequencies, to which the channels are to be allocated. These output frequencies are occupied frequencies of unwanted channels to be overlaid or free frequencies. According to the invention, channels are provided at the output of each converter module 40, which have a different frequency position compared to the frequency position at the input of the modules. As can be seen from Figure 10, at circuit point i, channels 72, 82, 77, and 89 occur in a frequency position, that is different from the frequency position of the channels at circuit points g and h. Channels 65, 68, 17 and 41 exist at circuit point m, which originate from circuit points I and j, also in different frequency positions. After the channels have been subjected to a mixing process in mixer 9, all selected channels originating from circuit points g, h, i and j are present at circuit point n, as shown in Figure 10, in frequency positions that differ from the original frequency positions. These channels are introduced via the feed source 11 into the amplifier 12, which amplifies the signal levels of the channels. Then, the channels present at circuit point n are mixed with the channels present at circuit point k in mixer 5. In this mixing process, the channels present at circuit point n are overlaid on the channels of the same frequency, that are present at circuit point k. The channels at circuit point n have a higher signal level of at least 15, but preferably 18 to 20 dB above the signal levels of the channels at circuit point k, which are to be overlaid. This level difference ensures that the channel, that overlays another channel, is received without interference from the channel that has been overlaid. After the mixing process has been carried out in the second mixer 5, one or more channels shown in Figure 10 will be received, these channels then being distributed via the single distribution cable 13. In this case, as illustrated in Figure 10, channel 65 is superimposed on channel 60 (cf. larger amplitude of 65 compared to 60), channel 72 on channel 36,

Asserted Claims	Carnero
	channel 68 on channel 44, channel 82 on channel 2, channel 77 on channel 6, channel 17 on channel 12, channel 89 on channel 18, and channel 41 on channel 24. Carnero at Fig. 10:  Carnero at Claims 3-4:

Asserted Claims	Carnero
	3. A system according to Claim 2, characterized in that the converter module (40) comprises at least two channel-specific converters (4), and that the channel-specific converters (4) in the converter module (40) are interconnected, in such a way, that an input (EC1) of a first converter module is connected to an input (EC2) of a second converter module, adjacent to the first converter module, and that an output (SC1) of the first converter module is connected to an output (SC2) of the second converter module. 4. A system according to Claim 3, characterized in that the connection, of the inputs of two adjacent channel-specific converters (4) and/or the connection of the outputs of two adjacent channel-specific converters (4), is realized by connecting bridges (7). To the extent Carnero does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Carnero alone or it would have been obvious to combine Carnero with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Carnero discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*: Carnero at 5:1-47: Each individual channel converter 4, the circuitry of which will be explained in detail in Figure 7, has two inputs and two outputs. As shown in Figures 3, 4, 5, 6 and 9, the channel-specific converters 4 of a converter module 40 are interconnected, in such a way, that an input (e.g., EC1 in Figure 7) of a first converter module is connected to the input (e.g., EC2) of a second converter module (not shown in Figure 7), adjacent to the first converter module. Likewise, an output (such as

Asserted Claims	Carnero
	SCI) of the first converter module is connected to the output (such as SC2) of the second converter module (daisy chain). This daisy-chain structure has the practical advantage, that not every individual channel converter 4 has to be connected to a down converter 2 via a separate cable 3, and that, furthermore, not every individual channel converter 4 has to be connected via a separate cable to a ("second") mixer (5), which is connected upstream of the distribution cable 13. It may be provided that each of the two inputs is respectively connected, e.g., via a respective known connecting bridge 7, to an input of an upstream channel-specific converter 4, or to the input of a downstream channel-specific converter 4. Likewise, with regard to the outputs, it can be provided that each of the two outputs is connected, for example, via a respective known connecting bridge 7, to an output of an upstream channel-specific converter 4 or to the output of a downstream channel-specific converter 4. Ideally, an identical housing is provided for each individual channel converter 4, i.e., a housing of the same spatial dimensions on which the input and output connections are arranged at the same locations. This allows the use of identical connecting bridges 7, each of which is used to establish an electrical connection either between two inputs or between two outputs. Furthermore, it may be provided that one input of a converter 4 (first converter 4 of a converter module 40, which is drawn on the right side of a converter module in figures 4 and 5, respectively) is connected to a cable 3, which transmits the signals generated by the down converters 2, or converted to the intermediate frequency range. One input of a converter 4 (last converter 4 of a converter module 40, which is drawn on the left in Figures 4 and 5) is connected to a supply source 11, which supplies the converters 4 and an amplifier 12 provided per signal processing unit 400. These channel-specific converters 4 receive on the input side the signals or channels in the intermediate frequency range, emitted by the down converters 2 and transmitted via the cables 3, and convert the signals or channels in the intermediate frequency range, as will still be described based on Figures 9 and 10.

Asserted Claims	Carnero
	Inputs of the channel-specific converters 4, which are not connected to the input of an adjacent converter or to which no cable 3 is connected, can be terminated with an ohmic resistor 8 of 75 ohms (cf. Figure 3, block B, reference number 8 above the converters 4; right converter module 40 in Figure 5; Figure 9, reference number 8 above the converters 4). Likewise, outputs of the channel-specific converters 4 can be terminated with an ohmic resistor 8 of 75 ohms (cf. Figure 3, block B, reference number 8 below the converters 4; right and left converter module 40 in Figure 5; Figures 6 and 9, reference number 8 below the converters 4). These are, in particular, the output of a first converter 4 (with respect to the signal flow) in a first converter module (right converter module in Figure 5), as well as the output of a last converter 4 (with respect to the signal flow) in a last converter module (left converter module in Figure 5). With each channel-specific converter 4, a channel is selected and converted from an input frequency, in the intermediate frequency range, to a predeterminable output frequency in the intermediate frequency range. As described earlier, multiple channel-specific converters 4, at least two, preferably four converters 4 may be integrated into a converter module 40. Two adjacent modules can be combined via a ("first") mixer 9. The output of the first mixer 9 is introduced into the feed source 11 and amplifier 12 arrangement by means of a connecting cable 10. The amplified signal is fed to the second mixer 5. The channel-specific converter 4 is preferably designed as follows: Carnero at 7:20-8:25: As shown in Figure 3, the distribution network C consists of a single distribution cable 13, on which all channels, that are FM modulated, are transmitted. The distribution cable 13 is



Asserted Claims	Carnero
	made up of a coaxial cable and runs to diverters 14, which output the signal to various user outlets 15. Figure 4 shows a signal processing unit 400 with one converter module 400 consisting of four channel-specific converters 4, while Figure 5 shows a signal processing unit 400 with two converter modules 400, each consisting of four channel-specific converters 4. In the system, according to the invention, the number of channel-specific converters 4 is equal to the number of channels coupled into the distribution cable 13, and transmitted to the user outlets 15, via the diverters 14. The channel-specific converters can be set to predeterminable input frequencies in the intermediate frequency range, and to predeterminable output frequencies in the intermediate frequency range. Figure 7 shows an example of a channel-specific converter 4. Two inputs EC1 and EC2 are electrically connected to each other and to an amplifier 42 via a directional coupler 41. The inputs EC1 and EC2 are mechanically designed, in such a way, that known connecting bridges (7 in Figure 4) can be used for connection to one input each of an adjacent channel-specific converter. In this way, several channel-specific converters can be integrated into one converter module. This type of connection thus consists in each of the two inputs EC1, EC2 being connected, e.g., via a respective known connection bridge, to an input of an upstream channel-specific converter 4 or to the input of a downstream channel-specific converter 4. Similarly, each of the two outputs SCI, SC2 of the converter 4 is respectively connected, for example, via a respective known connecting bridge, to an output of an upstream channel-specific converter 4 or to the output of a downstream channel-specific converter 4. This type of connection has the advantage of not requiring distributors, which would otherwise have to be connected downstream of the down converters 2, and connecting cables between these distributors and channel-specific converters. The amplifier 42 amplifies the supplied signals, for example, in the frequency band from 950 to 2,050 MHz. The signals are fed to a tracking filter 43 on the input side. This filter is

Asserted Claims	Carnero
	a bandpass filter tuned to the selected input channel frequency by means of a voltage, generated by a phase-locked loop (PLL) circuit 46. The circuit 46 is controlled by a microprocessor (MP) 49. A mixer 44 connected downstream of the tracking filter 43 is actuated by a local oscillator (OL) 45, which in turn is actuated by the PLL circuit 46. The mixer 44 converts the frequency of the selected channel present at inputs EC1 and EC2 to a frequency of 479.5 MHz. The signal formed by the mixer 44 is fed to a low-pass filter 47, whose cutoff frequency is 600 MHz, for example. This eliminates the signal from the local oscillator 45 and any unwanted signals formed during the mixing process. The signal is then filtered by means of a SAW 50 surface acoustic wave filter, which has, for example, a bandwidth of 27 MHz at a center frequency of 479.5 MHz. The amplifiers 48 and 51, which are connected upstream and downstream of the SAW (surface acoustic wave) filter, respectively, increase the signal level, in such a way, that the losses caused by the SAW filter 50 are compensated. The mixer 52 connected downstream of the amplifier 51 mixes the signal of the frequency 479.5 MHz, selected at the input, with a signal formed by a local oscillator (OL) 53. The local oscillator is controlled by a PLL circuit 54. The PLL circuit 54 is also controlled by the microprocessor 49. A tracking filter 55 is connected downstream of the mixer 52, which, like the filter 43, is a bandpass filter. The filter 55 eliminates the unwanted signals formed during the mixing done by the mixer 52. The output of filter 55 then carries the signal of the frequency-converted channel, which is fed to an amplifier 56. The gain of amplifier 56 is controllable, so that the levels of the frequency-converted channel signal can be set to pre-definable values (cf., for example, channels 1 and 5 in Figure 8)

Asserted Claims	Carnero
	A downstream directional coupler 57 feeds the amplified signal to the outputs SC1, SC2. The outputs SC1 and SC2 are mechanically designed, in such a way, that known connecting bridges (7 in Figure 4) can be used for connecting to one output each of an adjacent channel-specific converter. As shown in Figure 7, the converters 4 may include a microprocessor 49, that controls the PLL circuits 46 and 54 and determines the input and output frequency of the channel signal of the converters 4. Further, the microprocessor 49 may control the amplifier 56. An input unit 16 can be connected to the microprocessor 49, for example, via a 4-cable bus, through which the data of a pre-definable input and output frequency and/or control data for the amplifier 56 (signal amplification parameters) can be input into the microprocessor 49. The input unit 16 can have a control unit 162 (in particular, a microprocessor MP). A program assigned to the control unit 162 generates data as a function, for example, of the cutoff frequencies of the respective intermediate frequency range (950 MHz, 2,050 MHz), of channel bandwidths and channel spacings and signal levels of the channel signals, which corresponds to predefined technical specifications, and which is input into the microprocessor 49 of the channel-specific converter 4. The input unit 16 includes a keyboard 161, the control unit 162 and a display 163. The display shows data entered into the keypad 161, operator guidance information, and information indicating the state of the converter after it is configured by the data entered. The input unit 16 may be designed as a remote-controlled transmitter with a transmitting device, that transmits the data to be input to a receiver connected to the microprocessor 49 of the channel-specific converter. Carnero at 9:36-10:6: As shown in Figure 10, channels 70, 72, ...92, are located at circuit point g, channels 71, 73, ...93 are located at circuit point h, channels 65 - 69 are located at circuit point i, channels 49, 51...63, 33...47, 1, 3, ...31 are located at circuit point j, and channels 50, 52 ... 64; 34, 36, ... 48; 2, 4 ... 32 at circuit point k.

Asserted Claims	Carnero
	The desired channels are selected from all available channels at the switching points d - k. For example, channels 60, 36, 44, 2, 6, 12, 18, and 24 available at circuit point k are not processed further, while channels 65, 72, 68, 82, 77, 17, 89, and 41 available at circuit points g, h, i, j, are further processed instead. For this purpose, converter modules 40 are provided at the circuit points g, h, i, j, and the channel-specific converters 4 of the modules 40 are set to the input frequencies of each of the selected channels, and to the output frequencies, to which the channels are to be allocated. These output frequencies are occupied frequencies of unwanted channels to be overlaid or free frequencies. According to the invention, channels are provided at the output of each converter module 40, which have a different frequency position compared to the frequency position at the input of the modules. As can be seen from Figure 10, at circuit point i, channels 72, 82, 77, and 89 occur in a frequency position, that is different from the frequency position of the channels at circuit points g and h. Channels 65, 68, 17 and 41 exist at circuit point m, which originate from circuit points I and j, also in different frequency positions. After the channels have been subjected to a mixing process in mixer 9, all selected channels originating from circuit points g, h, i and j are present at circuit point n, as shown in Figure 10, in frequency positions that differ from the original frequency positions. These channels are introduced via the feed source 11 into the amplifier 12, which amplifies the signal levels of the channels. Then, the channels present at circuit point n are mixed with the channels present at circuit point k in mixer 5. In this mixing process, the channels present at circuit point n are overlaid on the channels of the same frequency, that are present at circuit point k. The channels at circuit point n have a higher signal level of at least 15, but preferably 18 to 20 dB above the signal levels of the channels at circuit point k, which are to be overlaid. This level difference ensures that the channel, that overlays another channel, is received without interference from the channel that has been overlaid.

Asserted Claims	Carnero
	After the mixing process has been carried out in the second mixer 5, one or more channels shown in Figure 10 will be received, these channels then being distributed via the single distribution cable 13. In this case, as illustrated in Figure 10, channel 65 is superimposed on channel 60 (cf. larger amplitude of 65 compared to 60), channel 72 on channel 36, channel 68 on channel 44, channel 82 on channel 2, channel 77 on channel 6, channel 17 on channel 12, channel 89 on channel 18, and channel 41 on channel 24. Carnero at Fig. 10:

Asserted Claims	Carnero
	 To the extent Carnero does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Carnero alone or it would have been obvious to combine Carnero with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

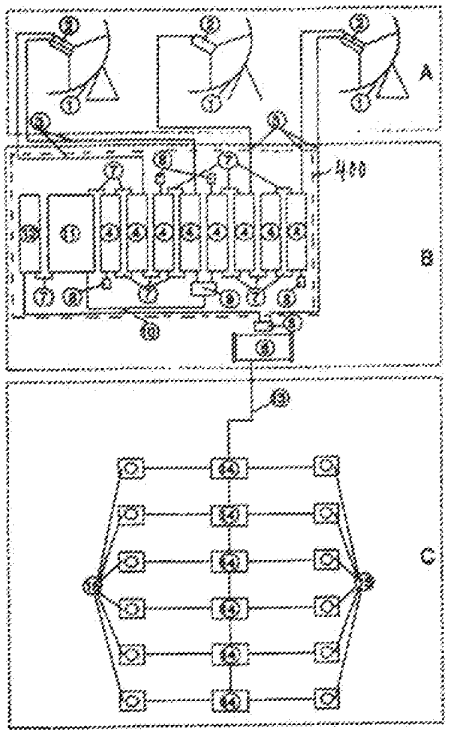
As shown in Figure 6, first signals formed by a converter module 40 (input E1), as well as second signals formed by down converters 2 (input E2), as well as third signals emitted by antennas receiving signals from terrestrial transmitters, can be fed to the second mixer 5. The distribution cable 13 is connected to this mixer 5 on the output side. Alternatively, an</td></tr>
</table>

Asserted Claims	Carnero
	amplifier 6 is provided downstream of the mixer 5, to which the distribution cable 13 is connected on the output side. As shown in Figure 3, the distribution network C consists of a single distribution cable 13, on which all channels, that are FM modulated, are transmitted. The distribution cable 13 is made up of a coaxial cable and runs to diverters 14, which output the signal to various user outlets 15. Carnero at 8:26-9:20: Figure 8 shows a second mixer 5, which is also shown in Figure 3, block B. For example, the second mixer 5 has three inputs E1, E2, E3 and an output S to which the distribution cable 13 is connected. The distribution cable 13 is preferably a coaxial cable, but an optical fiber may also be provided. Input E1 is directly connected by a cable to one or more converter modules 40. Input E2 is directly connected by a cable 3 to a down-converter (2 in Figure 3), while input E3 is connected to a system for receiving terrestrial channels. As shown in Figure 8 as an example, signals from channels 1, 2, 3, 4, 5 and 6 are fed to input E1. These signals originate from a satellite, have a bandwidth of 27 MHz and, as described, have been converted by channel-specific converters into the frequency band between 950 and 2,050 MHz. Input E2 is fed with signals from channels 7, 8, 9, 10, 11, 12, 13 and 14, which originate from a satellite, have a bandwidth of 27 MHz, and have been converted by channel-specific converters in the frequency band between 950 and 2,050 MHz, as described. Input E3 provides 6 terrestrial TV channels with 8 MHz bandwidth, in the frequency band between 47 and 860 MHz. The signals of the channels coming in at input E1 are supplied by the channel-specific converters 4, in which the frequency conversion and the generation of the respective levels



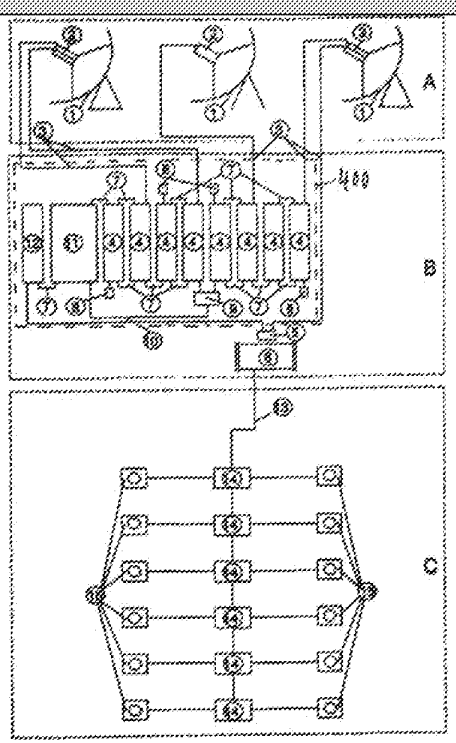
Asserted Claims	Carnero
	are carried out, with regard to the coupling of the signals via the mixer output S into the distribution cable 13. Channels 2, 4 and 6, which arrive at input E1, have been frequency-converted in the channel-specific converters 4, in such a way, that no channels of the same frequencies arrive at input E2. Channels 1 and 3 at input E1 are allocated in frequencies between the undesired channels 7 and 8 or 9 and 10, which come in at input E2. The signal or power level of channel 1 is set to a value at least 15 dB above the corresponding level of channels 7 and 8. The signal or power level of channel 3 is set to a value at least 15 dB above the corresponding level of channels 9 and 10. Channel 5 of input E1 is set to the same frequency as the non-desired channel 12 at input E2, with the signal or power level of channel 5 being at least 20 dB above the corresponding level of channel 12. The level difference (at least 15 dB or at least 20 dB) depends on the frequencies of the overlaying channel and the frequency of the channel(s) to be overlaid: at a different frequency (cf. channel 1 overlaying channels 7 and 8) the level difference is at least 15 dB; at the same frequency (cf. channel 5 overlaying channel 12) the level difference is at least 20 dB. The channels at the inputs E1, E2 and E3 of mixer 5, which are configured in this way, with respect to frequency and level, are coupled by the mixer at output S into the distribution cable 13, in the arrangement shown in Figure 8: - in the frequency band between 47 and 860 MHz, the same channels are available at output S, in the same frequency position, and with the same levels as at input E3; - in the frequency band between 950 and 2,050 MHz, channels 7 and 8 of input E2 are overlaid at output S, by channel 1 of input E1. Since channel 1 is set to a signal level, that is at least 15 dB above the levels of channels 7 and 8, only channel 1 is visible to the system user, without channels 7 and 8 causing interference.

Asserted Claims	Carnero
	Likewise, at output S, channels 9 and 10 of input E2 are overlaid by channel 3 of input E1. In addition, channel 5 of input E1 is coupled into distribution cable 13 at output S, in the frequency position of channel 12 of input E2, with channel 5 overlapping channel 12, because the signal level of channel 5 is at least 20 dB above channel 12. In addition, channel 4 (originally at input E1) is coupled into distribution cable 13 between channels 3 (originally at input E1) and 11 (originally at input E2), and channel 6 (originally at input E1) is coupled between channels 13 (originally at input E2) and 14 (originally at input E2). Channels 4 and 6 are thus inserted into free frequency positions at input E2 Carnero at Fig. 8:

Asserted Claims	Carnero
	 Figur 5 Carnero at 10:1-5: After the mixing process has been carried out in the second mixer 5, one or more channels shown in Figure 10 will be received, these channels then being distributed via the single distribution cable 13. In this case, as illustrated in Figure 10, channel 65 is superimposed on channel 60 (cf. larger amplitude of 65 compared to 60), channel 72 on channel 36, channel 68 on channel 44, channel 82 on channel 2, channel 77 on channel 6, channel 17 on channel 12, channel 89 on channel 18, and channel 41 on channel 24.

Asserted Claims	Carnero
	Carnero at Fig. 10:  Carnero at Claim 10: 10. A system according to any one of the preceding claims, characterized in that the system includes a second mixer (5), having at least two inputs (E1, E2, E3), that one of the inputs (E1) is connectable to the output of the converter module (40), that another input (E2, E3) is connectable to a down converter (LNA/LNB 2), and that the second mixer (5) has an output (S), to which the distribution cable (13) is can be connected.

Asserted Claims	Carnero
	To the extent Carnero does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Carnero alone or it would have been obvious to combine Carnero with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[e] wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs.	Carnero discloses, explicitly and/or inherently, wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs. *See, e.g.*: Carnero at page 4: The signal distribution system shown in the drawings, as well as in Figure 3, consists of three blocks A, B and C. Block A is a signal generator, block B is a head device with a signal processing unit and block C represents the distribution network. Blocks A, B and C are designed as follows: 1. Block A is a signal generator consisting of at least one antenna 1 and known down converters 2 (low-noise amplifier LNA, low-noise block converter LNB). The received signals may originate from different broadcast and/or telecommunications satellites and/or have different polarities (horizontal, vertical). The down-converters 2 convert the received signals, in an already known way, from the received frequency range of, for example, 11.7 - 12.5 GHz; 10.7 - 11.7 GHz; 12.5 - 12.75 GHz or preferably 10.7 - 12.5 GHz into an intermediate frequency range of, for example, 950 - 1760 MHz or preferably 950 MHz and 2,050 MHz.



Asserted Claims	Carnero
	2. Block B is a head device with a signal processing device 400, in which channel-specific converters 4 are arranged. The channel-specific converters 4 are described in more detail, in particular, with reference to Figure 7. Various designs of the signal processing device 400 are shown in Figures 3, 4, 5, and 6; 3. The distribution network C has a single distribution cable 13, through which the signals are transmitted to user outlets 15, via tapping or diverters 14. Carnero at Fig. 3: 

Asserted Claims	Carnero
	Carnero at 9:15-20: Therefore, channels in the frequency band from 47 to 860 MHz and channels 1, 2, 3, 4, 11, 5, 13, 6 and 14 in the frequency band from 950 to 2,050 MHz are made available to the system user. Similarly, channels 7, 8, 9, 10 and 12 are transmitted on distribution cable 13. However, these channels are overlaid, so that they are not made available to the system user. With the signal level difference of at least 15 dB provided according to the invention, the overlapping channels can be displayed in good reception quality in the terminals, that can be connected to the user outlets. To the extent Carnero does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Carnero alone or it would have been obvious to combine Carnero with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
10. The signal distribution system of claim 9 wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output.	Carnero discloses, explicitly and/or inherently, wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output. *See* claim 9, *supra*. *See, e.g.*: Carnero at 3:48-53: The channel-specific converters may each have a microprocessor, that controls at least one oscillator. The microprocessor allows a converter-external input device to be detachably connected to the microprocessor and data to be input to the converter and the microprocessor, respectively, designating a predeterminable input channel frequency and a predeterminable output channel frequency. In this way, the channel-specific converters can be easily set to a pre-definable input frequency and a pre-definable output frequency, by

Asserted Claims	Carnero
	which the frequency conversion of a channel is determined. The converter-external input device can also be designed as a remote-controlled transmitter. Carnero at 7:55-60: The mixer 52 connected downstream of the amplifier 51 mixes the signal of the frequency 479.5 MHz, selected at the input, with a signal formed by a local oscillator (OL) 53. The local oscillator is controlled by a PLL circuit 54. The PLL circuit 54 is also controlled by the microprocessor 49. A tracking filter 55 is connected downstream of the mixer 52, which, like the filter 43, is a bandpass filter. The filter 55 eliminates the unwanted signals formed during the mixing done by the mixer 52. The output of filter 55 then carries the signal of the frequency-converted channel, which is fed to an amplifier 56. Carnero at 8:4-25: A downstream directional coupler 57 feeds the amplified signal to the outputs SC1, SC2. The outputs SC1 and SC2 are mechanically designed, in such a way, that known connecting bridges (7 in Figure 4) can be used for connecting to one output each of an adjacent channel-specific converter. As shown in Figure 7, the converters 4 may include a microprocessor 49, that controls the PLL circuits 46 and 54 and determines the input and output frequency of the channel signal of the converters 4. Further, the microprocessor 49 may control the amplifier 56. An input unit 16 can be connected to the microprocessor 49, for example, via a 4-cable bus, through which the data of a pre-definable input and output frequency and/or control data for the amplifier 56 (signal amplification parameters) can be input into the microprocessor 49. The input unit 16 can have a control unit 162 (in particular, a microprocessor MP). A program assigned to the control unit 162 generates data as a function, for example, of the cutoff frequencies of the respective intermediate frequency range (950 MHz, 2,050 MHz), of channel bandwidths and channel spacings and signal levels of the channel signals, which corresponds to predefined technical specifications, and which is input into the microprocessor 49 of the channel-specific converter 4. The input unit 16 includes a

Asserted Claims	Carnero
	keyboard 161, the control unit 162 and a display 163. The display shows data entered into the keypad 161, operator guidance information, and information indicating the state of the converter after it is configured by the data entered. The input unit 16 may be designed as a remote-controlled transmitter with a transmitting device, that transmits the data to be input to a receiver connected to the microprocessor 49 of the channel-specific converter. Carnero at Claims 6-7: 6. A system according to any one of the preceding claims, characterized in that the channel-specific converter (4) includes a microprocessor (49) controlling at least one oscillator (45, 53) of the channel-specific converter (4) and/or an amplifier (56) of the channel-specific converter (4). 7. A system according to claim 6, characterized in that the microprocessor (49) of the channel-specific converter (4) is connectable to an input device (16) external to the converter, via which data can be input, that designate a predeterminable input channel frequency and a predeterminable output channel frequency and/or signal gain parameters for controlling the amplifier (56). To the extent Carnero does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Carnero alone or it would have been obvious to combine Carnero with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
11. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network.	Carnero discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network. *See* claim 10, *supra*. *See, e.g.*:

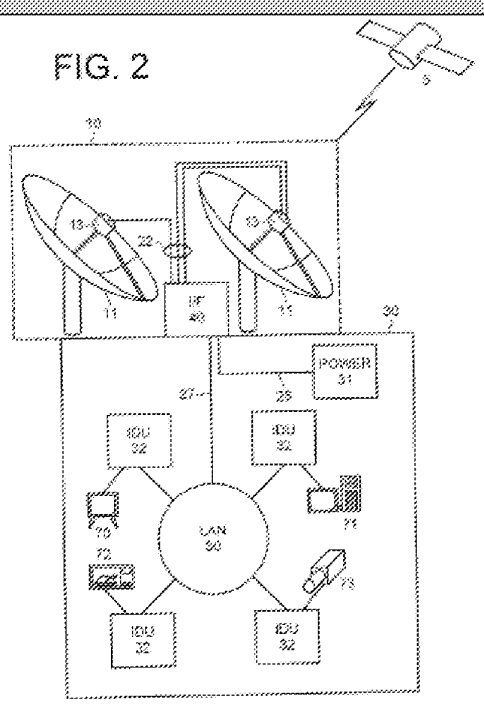
Asserted Claims	Carnero
	Carnero at page 4: The signal distribution system shown in the drawings, as well as in Figure 3, consists of three blocks A, B and C. Block A is a signal generator, block B is a head device with a signal processing unit and block C represents the distribution network. Blocks A, B and C are designed as follows: 1. Block A is a signal generator consisting of at least one antenna 1 and known down converters 2 (low-noise amplifier LNA, low-noise block converter LNB). The received signals may originate from different broadcast and/or telecommunications satellites and/or have different polarities (horizontal, vertical). The down-converters 2 convert the received signals, in an already known way, from the received frequency range of, for example, 11.7 - 12.5 GHz; 10.7 - 11.7 GHz; 12.5 - 12.75 GHz or preferably 10.7 - 12.5 GHz into an intermediate frequency range of, for example, 950 - 1760 MHz or preferably 950 MHz and 2,050 MHz. 2. Block B is a head device with a signal processing device 400, in which channel-specific converters 4 are arranged. The channel-specific converters 4 are described in more detail, in particular, with reference to Figure 7. Various designs of the signal processing device 400 are shown in Figures 3, 4, 5, and 6; 3. The distribution network C has a single distribution cable 13, through which the signals are transmitted to user outlets 15, via tapping or diverters 14. Carnero at Fig. 3:

Asserted Claims	Carnero
	 To the extent Carnero does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Carnero alone or it would have been obvious to combine Carnero with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
12. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the ODU and the translation table is	Carnero discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network.

Asserted Claims	Carnero
communicated to devices in the network.	*See* claim 10, *supra*. *See, e.g.*: Carnero at 3:48-53: The channel-specific converters may each have a microprocessor, that controls at least one oscillator. The microprocessor allows a converter-external input device to be detachably connected to the microprocessor and data to be input to the converter and the microprocessor, respectively, designating a predeterminable input channel frequency and a predeterminable output channel frequency. In this way, the channel-specific converters can be easily set to a pre-definable input frequency and a pre-definable output frequency, by which the frequency conversion of a channel is determined. The converter-external input device can also be designed as a remote-controlled transmitter. Carnero at 8:4-25: A downstream directional coupler 57 feeds the amplified signal to the outputs SC1, SC2. The outputs SC1 and SC2 are mechanically designed, in such a way, that known connecting bridges (7 in Figure 4) can be used for connecting to one output each of an adjacent channel-specific converter. As shown in Figure 7, the converters 4 may include a microprocessor 49, that controls the PLL circuits 46 and 54 and determines the input and output frequency of the channel signal of the converters 4. Further, the microprocessor 49 may control the amplifier 56. An input unit 16 can be connected to the microprocessor 49, for example, via a 4-cable bus, through which the data of a pre-definable input and output frequency and/or control data for the amplifier 56 (signal amplification parameters) can be input into the microprocessor 49. The input unit 16 can have a control unit 162 (in particular, a microprocessor MP). A program assigned to the control unit 162 generates data as a function, for example, of the cutoff frequencies of the respective intermediate frequency range (950 MHz, 2,050 MHz), of channel bandwidths and channel spacings and signal levels of the channel signals, which corresponds to predefined technical specifications, and which is input into the

Asserted Claims	Carnero
	microprocessor 49 of the channel-specific converter 4. The input unit 16 includes a keyboard 161, the control unit 162 and a display 163. The display shows data entered into the keypad 161, operator guidance information, and information indicating the state of the converter after it is configured by the data entered. The input unit 16 may be designed as a remote-controlled transmitter with a transmitting device, that transmits the data to be input to a receiver connected to the microprocessor 49 of the channel-specific converter. Carnero at Claims 6-7: 6. A system according to any one of the preceding claims, characterized in that the channel-specific converter (4) includes a microprocessor (49) controlling at least one oscillator (45, 53) of the channel-specific converter (4) and/or an amplifier (56) of the channel-specific converter (4). 7. A system according to claim 6, characterized in that the microprocessor (49) of the channel-specific converter (4) is connectable to an input device (16) external to the converter, via which data can be input, that designate a predeterminable input channel frequency and a predeterminable output channel frequency and/or signal gain parameters for controlling the amplifier (56). To the extent Carnero does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Carnero alone or it would have been obvious to combine Carnero with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Davis '055



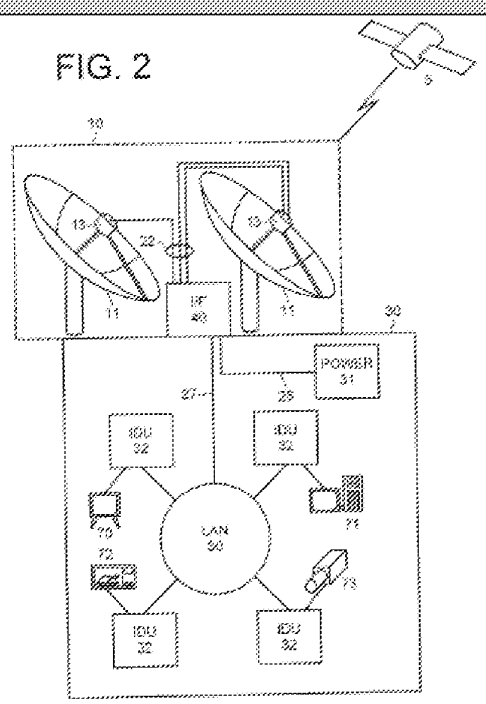
U.S. Patent Pub. No. 2002/0154,055 ("Davis '055") was filed on April 15, 2002 and published on October 24, 2002, and claims priority to U.S. Provisional Patent No. 60/284,593, which was filed on April 18, 2001. Davis '055 therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(e). For the reasons listed below, Davis '055 invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Davis '055
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Davis '055 discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*: Davis '055 at Abstract:

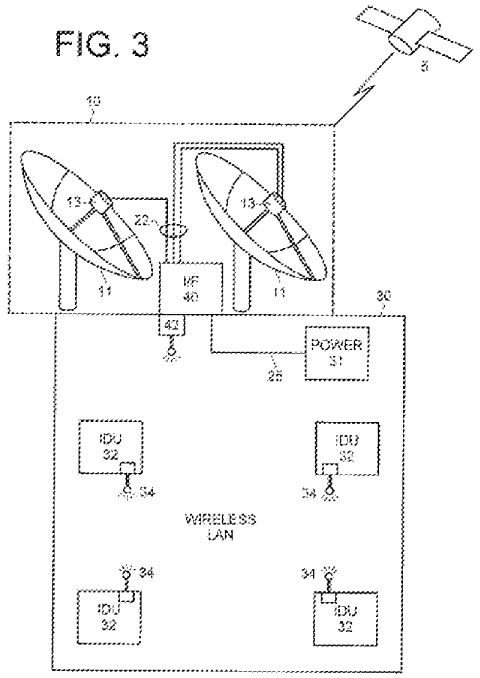
[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.

Asserted Claims	Davis '055
	A satellite communication system including an interface device for distributing satellite signals received from an outdoor unit (ODU) to a plurality of indoor units (IDUs) connected to a local area network (LAN), at a particular site. Only two cables, a power cable and a cable connected to the LAN, must be installed between the interface device and the site containing the IDUs. Accordingly, the installation of IDUs at a site is simplified and has the flexibility of allowing future satellite based services to be added without requiring the installation of new cables between the ODU and the IDUs. The satellite communication system also permit flexibility among connected devices, including to which other devices they are connected, how they are connected to other devices and what types of connections are used. Davis '055 at [0002]: This invention relates generally to the connection of a satellite antenna to multiple indoor units (IDUs), and more specifically, to an interface which connects at least one satellite antenna to multiple indoor units by means of a local area network (LAN). Davis '055 at [0013]: The present invention provides an interface that connects the plurality of LNB outputs to a local area network (LAN), which is connected to each IDU at a particular site. In particular, for each LNB at the ODU side, the interface of the present invention includes a receiver that converts the radio frequency (RF) signal from the LNB output into digital baseband information. This digital baseband information from each LNB output can be filtered, compressed and encrypted by the interface before being multiplexed together and sent by means of the LAN to the corresponding IDUs. The data can be sent to directly to its intended IDU using point-to-point communications, or alternatively, can be broadcast to each IDU. Davis '055 at [0014]: A first aspect of the present invention embodies an apparatus acting as an interface between a satellite antenna and a plurality of IDUs in a satellite communication system.

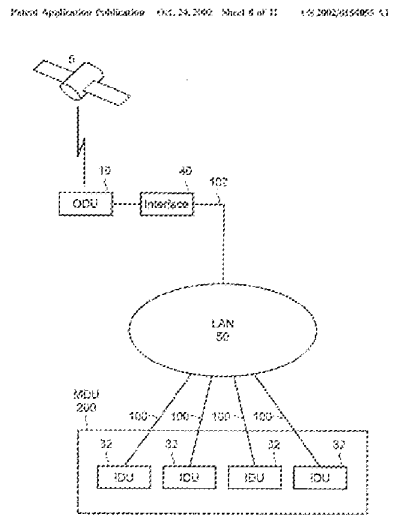
Asserted Claims	Davis '055
	This interface device includes a cable connection to each LNB output of the antenna, similar to a conventional multiswitch. Unlike a multiswitch, however, the interface device requires at most two additional cables, regardless of the number of IDUs in the system. One of these cables connects the interface device to a power source, while the other cable is a connection to a wired LAN, which is further connected to all of the IDUs. In this aspect, the interface device may include a processor that runs a set of protocols for controlling the transmission of data over the network. Further, the interface device may be built into the satellite antenna, or alternatively, may be configured as a standalone device within or outside of a building housing the IDUs. Davis '055 at [0037]: FIG. 2 illustrates an exemplary embodiment of the present invention where an interface device 40 connects the LNB 13 of an ODU 10 to multiple IDUs in conjunction with a wired LAN 50. The ODU 10 includes one or more satellite antennas 11, each of which includes one (or more) LNB 13. The LNB outputs are then connected via cables 22 to the interface device 40. Interface device 40 includes two output cables, including a power cable 25 connected to power source 31 within site 30, and a LAN connection 27 that is connected to LAN 50 running through site 30. The LAN 50 is connected to a plurality of IDUs 32. FIG. 2 as illustrated shows a dedicated cable 27 for the LAN connection. An existing cable, such as power cable 25, could also be used for the LAN connection. Davis '055 at Fig. 2:



Asserted Claims	Davis '055
	 Davis '055 at [0038]: The interface device 40 may be configured as part of the ODU 10, as shown in FIG. 2, and may even be integrated into a satellite antenna 11. Alternatively, the interface device 40 may be located apart from the ODU 10, either inside the building 30 (such as an attic) or at another outdoor location (such as on the roof). The interface device 40 may receive a single cable 22 from each LNB 13 at ODU 10. The interface device 40 may be connected to the ODU 10 via transmission cables (not shown). The transmission cables may allow the interface device 40 to send a signal to a satellite antenna 11, which is configured to transmit the signal to another site via satellite 5.



Asserted Claims	Davis '055
	Davis '055 at [0039]: As shown in FIG. 2, each IDU 32 is associated with one or more satellite services. Such services may include satellite television 70, satellite based Internet service for a device 71, diagnostics/maintenance of appliances 72, and home security 73. Services such as appliance diagnostics/maintenance 72 and home security 73, may require data to be measured or collected at their corresponding IDUs 32 and transmitted back to a central processing location (not shown) for analysis. Conventional satellite communication systems (e.g., the system illustrated in FIG. 1) would require both a receiving and transmitting cable to connect these IDUs 32 to the multiswitch 20. However, by connecting the interface device 40 to each IDU 32 via LAN 50, the interface device 40 can both transmit and receive data from all of the IDUs 32 connected to a single data bus. Davis '055 at Claim 12: The satellite communication system of claim 1, wherein at least one of said IDUs comprises a receiver for a satellite television application. *See also* U.S. Provisional Patent No. 60/284,593 ("Davis Provs.") at 3: Current satellite anntennas use cables to connect the antenna with what is commonly called the "indoor unit", the device that the user connects to to send/receive data. (Data can include digitized A/V material, such as DIRECTV). As satellite based services evolve, more and more cables are required. Units are now being built that have 2 receive cables, or a receive and transmit cable. In the short term the number of cables could increase to 5 or 10 with currently envisioned services. This invention replaces these cables with one (power) or two (power plus phone, or power plus wired LAN), using industry standard interface mechanisms, while simultaneously greatly increasing the flexibility of the installation to allow future services without adding any new cables.



Asserted Claims	Davis '055
	EXPLAIN THE PURPOSE AND ADVANTAGES OF YOUR INVENTION (WHAT WILL THE INVENTION .... DO BETTER THAN DONE PREVIOUSLY?) Minimizes number of cables to be run from the outdoor unit (maximum 2); • Minimizes cables to be run between outdoor unit and any particular indoor unit • Allows many indoor units to access one outdoor unit. • Allows new indoor units/new services to be added after initial installation without any new cables • Greatly simplifies installation in MDU's (Multi dwelling units) • Enables subscription services like home security and diagnostics/maintenance of appliances. Davis Provis. At 5: The interface between the indoor units(s) and outdoor unit of DirecPC/DIRECTV/ DirecWay/Spaceway all could use this invention. ... Wireless connections between ODU and IOU have been proposed before. As far as I know, these have been analog repeaters of the signals on the IDU/ODU cable, and performing 6ollocated6 [sic] the same functions as the cable. Using a LAN allows multiple access, and greatly increased flexibility for future services via an industry standard method. Davis Provis. At 7:

Asserted Claims	Davis '055
	Current practice will often use what is called a "multiswitch" in an installation. This is a device that has one cable for each LNB on the ODU side, and one cable for each IDU satellite input on the IDU side. The multiswitch is responsible for connecting the correct LNB to each IDU as commanded by the IDU. This multiswitch can be 7ollocated with the antenna, or remotely mounted. This invention uses the same connectivity as the multiswitch on the ODU side (one cable for each LNB) but replaces the multiswitch to IDU cable with a LAN. To do this, this invention has receivers inside for each LNB that convert the RF input to digital base band information. This digital baseband information can be filtered to discard unwanted information, can be compressed if it is not already, and can be encrypted for privacy if desired. The digital baseband data is then multiplexed together and sent via the LAN to the receiving IDU (s). Data can be sent point to point or broadcast. Data to be transmitted over the satellite and control data for the receivers in this invention is sent over the LAN to the unit from the transmitting IDU. A cable connection exists from this invention to the transmitter on the ODU, as is current practice. To the extent Davis '055 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Davis '055 alone or it would have been obvious to combine Davis '055 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[a] a gateway in communication with the ODU and at least one set top box (STB);	Davis '055 discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Davis '055 at [0037]:

Asserted Claims	Davis '055
	FIG. 2 illustrates an exemplary embodiment of the present invention where an interface device 40 connects the LNB 13 of an ODU 10 to multiple IDUs in conjunction with a wired LAN 50. The ODU 10 includes one or more satellite antennas 11, each of which includes one (or more) LNB 13. The LNB outputs are then connected via cables 22 to the interface device 40. Interface device 40 includes two output cables, including a power cable 25 connected to power source 31 within site 30, and a LAN connection 27 that is connected to LAN 50 running through site 30. The LAN 50 is connected to a plurality of IDUs 32. FIG. 2 as illustrated shows a dedicated cable 27 for the LAN connection. An existing cable, such as power cable 25, could also be used for the LAN connection. Davis '055 at Fig. 2:

Asserted Claims	Davis '055
	• Allows new indoor units/new services to be added after initial installation without any new cables • Greatly simplifies installation in MDU's (Multi dwelling units) • Enables subscription services like home security and diagnostics/maintenance of appliances. Davis Provis. at 5: The interface between the indoor units(s) and outdoor unit of DirecPC/DIRECTV/ DirecWay/Spaceway all could use this invention. … Wireless connections between ODU and IOU have been proposed before. As far as I know, these have been analog repeaters of the signals on the IDU/ODU cable, and performing esentially [sic] the same functions as the cable. Using a LAN allows multiple access, and greatly increased flexibility for future services via an industry standard method. Davis Provis. at 7: Current practice will often use what is called a "multiswitch" in an installation. This is a device that has one cable for each LNB on the ODU side, and one cable for each IDU satellite input on the IDU side. The multiswitch is responsible for connecting the correct LNB to each IDU as commanded by the IDU. This multiswitch can be colocated with the antenna, or remotely mounted. This invention uses the same connectivity as the multiswitch on the ODU side (one cable for each LNB) but replaces the multiswitch to IDU cable with a LAN. To do this, this invention has receivers inside for each LNB that convert the RF input to digital base band information. This digital baseband information can be filtered to discard unwanted

Asserted Claims	Davis '055
	information, can be compressed if it is not already, and can be encrypted for privacy if desired. The digital baseband data is then multiplexed together and sent via the LAN to the receiving IDU (s). Data can be sent point to point or broadcast. Data to be transmitted over the satellite and control data for the receivers in this invention is sent over the LAN to the unit from the transmitting IDU. A cable connection exists from this invention to the transmitter on the ODU, as is current practice. To the extent Davis '055 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Davis '055 alone or it would have been obvious to combine Davis '055 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information;	Davis '055 discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*: Davis '055 at [0013]: The present invention provides an interface that connects the plurality of LNB outputs to a local area network (LAN), which is connected to each IDU at a particular site. In particular, for each LNB at the ODU side, the interface of the present invention includes a receiver that converts the radio frequency (RF) signal from the LNB output into digital baseband information. This digital baseband information from each LNB output can be filtered, compressed and encrypted by the interface before being multiplexed together and sent by means of the LAN to the corresponding IDUs. The data can be sent to directly to

Asserted Claims	Davis '055
	its intended IDU using point-to-point communications, or alternatively, can be broadcast to each IDU. Davis '055 at [0036]: In the satellite communication system illustrated in FIG. 1, the satellite signals may already be encrypted when they are received by ODU 10 and sent to the IDUs 32A and 32B. Accordingly, IDUs 32A and 32B may comprise Integrated Receiver Decoders (IRDs), which include a processor for decrypting or descrambling the received signal. Further, IRDs may perform other functions, such as providing an electronic program guide (EPG) or recording certain programs on satellite TV signals. Davis '055 at [0037]: FIG. 2 illustrates an exemplary embodiment of the present invention where an interface device 40 connects the LNB 13 of an ODU 10 to multiple IDUs in conjunction with a wired LAN 50. The ODU 10 includes one or more satellite antennas 11, each of which includes one (or more) LNB 13. The LNB outputs are then connected via cables 22 to the interface device 40. Interface device 40 includes two output cables, including a power cable 25 connected to power source 31 within site 30, and a LAN connection 27 that is connected to LAN 50 running through site 30. The LAN 50 is connected to a plurality of IDUs 32. FIG. 2 as illustrated shows a dedicated cable 27 for the LAN connection. An existing cable, such as power cable 25, could also be used for the LAN connection. Davis '055 at Fig. 2:

Asserted Claims	Davis '055
	 Davis '055 at [0038]: The interface device 40 may be configured as part of the ODU 10, as shown in FIG. 2, and may even be integrated into a satellite antenna 11. Alternatively, the interface device 40 may be located apart from the ODU 10, either inside the building 30 (such as an attic) or at another outdoor location (such as on the roof). The interface device 40 may receive a single cable 22 from each LNB 13 at ODU 10. The interface device 40 may be connected to the ODU 10 via transmission cables (not shown). The transmission cables may allow the interface device 40 to send a signal to a satellite antenna 11, which is configured to transmit the signal to another site via satellite 5.

Asserted Claims	Davis '055
	Davis '055 at [0039]: As shown in FIG. 2, each IDU 32 is associated with one or more satellite services. Such services may include satellite television 70, satellite based Internet service for a device 71, diagnostics/maintenance of appliances 72, and home security 73. Services such as appliance diagnostics/maintenance 72 and home security 73, may require data to be measured or collected at their corresponding IDUs 32 and transmitted back to a central processing location (not shown) for analysis. Conventional satellite communication systems (e.g., the system illustrated in FIG. 1) would require both a receiving and transmitting cable to connect these IDUs 32 to the multiswitch 20. However, by connecting the interface device 40 to each IDU 32 via LAN 50, the interface device 40 can both transmit and receive data from all of the IDUs 32 connected to a single data bus. Davis '055 at [0048]: The network protocols and services unit 45 may also receive packets from the LAN 50, via LAN interface 46, which contain data to be transmitted to another site 30 over the satellite network. Accordingly, the network protocols and services unit 45 can reassemble the packets into the original digital baseband signal. The reassembled signal may be sent to transmission signal processing unit 42, where it is processed and converted back into an RF signal, suitable for transmission. The converted RF signal is then sent back to a transmitting antenna via LNB interface 41 and cable 22. Davis '055 at [0055]: By utilizing the wired LAN 50 of the present invention, a plurality of IDUs 32 (PCs) configured for satellite Internet service can receive content from the same satellite antenna 11 without requiring a plurality of cables running from the ODU 10 to the IDU. Further, each IDU 32 can transmit requests over the same cable connection, which connects the data bus of LAN 50 to the ISP.

Asserted Claims	Davis '055
	Davis '055 at [0065]: According to this exemplary embodiment, a signal is transmitted via satellite 5 to the ODU 10, which sends the received signal to the interface device 40. The interface device 40 then sends the satellite data to the server application 36, which stores the data in storage device 38. Any of the IDUs 32 may send requests to the server application 36 over the wired LAN 50 for accessing the data stored in storage device 38. If the server application 36 accepts a request from an IDU 32, the data will be downloaded to the requesting IDU 32 over the LAN 50. In a further exemplary embodiment, the server application 36 may accept an IDU's request only after the user of the IDU 32 agrees to pay a fee for downloading the requested data. Davis '055 at [0073]: FIG. 10 illustrates yet another embodiment of the present invention, where the interface 40 acts as an converter and/or concentrator. As illustrated in FIG. 10, the interface 40 may receive information from any number of connections, such as DSL, satellite, cable, among others. The interface 40 may also receive information from other wide area products and from other devices such as CD players. The interface 40 may convert/concentrate the received information for forwarding to LAN 50. Interface 40 may also include outgoing connections for sending control/request information to any of the information sources illustrated in FIG. 10. *See also* Davis Provs. at 3: Current satellite anntennas use cables to connect the antenna with what is commonly called the "indoor unit", the device that the user connects to to send/receive data. (Data can include digitized A/V material, such as DIRECTV). As satellite based services evolve, more and more cables are required. Units are now being built that have 2 receive cables, or a receive and transmit cable. In the short term the number of cables could increase to 5 or 10 with currently envisioned services. This invention replaces these cables with one (power) or two (power plus phone, or power plus wired LAN), using industry standard

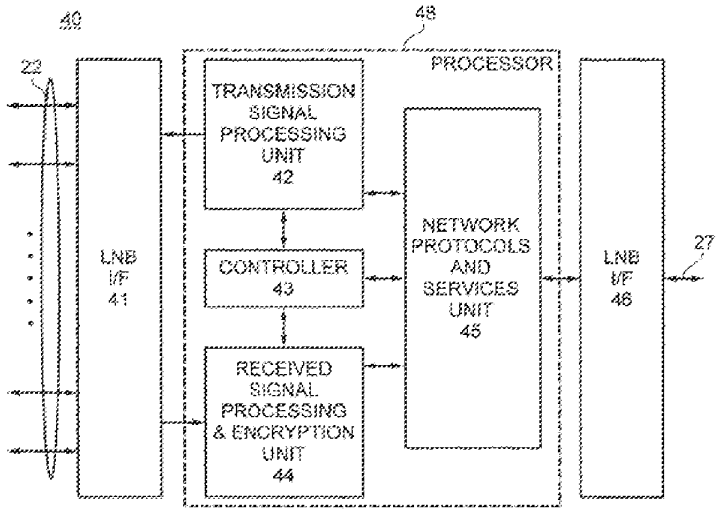
	interface mechanisms, while simultaneously greatly increasing the flexibility of the installation to allow future services without adding any new cables. Davis Provis. at 5: The interface between the indoor units(s) and outdoor unit of DirecPC/DIRECTV/ DirecWay/Spaceway all could use this invention. … Wireless connections between ODU and IOU have been proposed before. As far as I know, these have been analog repeaters of the signals on the IDU/ODU cable, and performing esentially [sic] the same functions as the cable. Using a LAN allows multiple access, and greatly increased flexibility for future services via an industry standard method. Davis Provis. at 7: Current practice will often use what is called a "multiswitch" in an installation. This is a device that has one cable for each LNB on the ODU side, and one cable for each IDU satellite input on the IDU side. The multiswitch is responsible for connecting the correct LNB to each IDU as commanded by the IDU. This multiswitch can be colocated with the antenna, or remotely mounted. This invention uses the same connectivity as the multiswitch on the ODU side (one cable for each LNB) but replaces the multiswitch to IDU cable with a LAN. To do this, this invention has receivers inside for each LNB that convert the RF input to digital base band information. This digital baseband information can be filtered to discard unwanted information, can be compressed if it is not already, and can be encrypted for privacy if desired. The digital baseband data is then multiplexed together and sent via the LAN to the receiving IDU (s). Data can be sent point to point or broadcast.

Asserted Claims	Davis '055
	Data to be transmitted over the satellite and control data for the receivers in this invention is sent over the LAN to the unit from the transmitting IDU. A cable connection exists from this invention to the transmitter on the ODU, as is current practice. To the extent Davis '055 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Davis '055 alone or it would have been obvious to combine Davis '055 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Davis '055 discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*: Davis '055 at [0013]: The present invention provides an interface that connects the plurality of LNB outputs to a local area network (LAN), which is connected to each IDU at a particular site. In particular, for each LNB at the ODU side, the interface of the present invention includes a receiver that converts the radio frequency (RF) signal from the LNB output into digital baseband information. This digital baseband information from each LNB output can be filtered, compressed and encrypted by the interface before being multiplexed together and sent by means of the LAN to the corresponding IDUs. The data can be sent to directly to its intended IDU using point-to-point communications, or alternatively, can be broadcast to each IDU. Davis '055 at [0045]: The operation of the interface device 40 will now be described in connection with FIGS. 2 and 5. Once the RF signal transmitted by a satellite 5 is received into a particular LNB 13,

Asserted Claims	Davis '055
	the signal may be sent to a corresponding input/output port of LNB interface 41. The RF signal may then be sent to the received signal processing and encryption unit 44, where the signal is converted into a digital baseband signal. The received signal processing and encryption unit 44 may perform other signal processing on the baseband signal, such as filtering noise and other unwanted information. In addition, the received signal processing and encryption unit 44 may encrypt the digital baseband signal, such that only IDUs having a certain decryption key will be able to decrypt the signal and access the information contained therein. *See also* Davis Provs. at 3: Current satellite anntennas use cables to connect the antenna with what is commonly called the "indoor unit", the device that the user connects to to send/receive data. (Data can include digitized A/V material, such as DIRECTV). As satellite based services evolve, more and more cables are required. Units are now being built that have 2 receive cables, or a receive and transmit cable. In the short term the number of cables could increase to 5 or 10 with currently envisioned services. This invention replaces these cables with one (power) or two (power plus phone, or power plus wired LAN), using industry standard interface mechanisms, while simultaneously greatly increasing the flexibility of the installation to allow future services without adding any new cables. EXPLAIN THE PURPOSE AND ADVANTAGES OF YOUR INVENTION (WHAT WILL THE INVENTION .... DO BETTER THAN DONE PREVIOUSLY?) • Minimizes number of cables to be run from the outdoor unit (maximum 2); • Minimizes cables to be run between outdoor unit and any particular indoor unit. • Allows many indoor units to access one outdoor unit.



Asserted Claims	Davis '055
	• Allows new indoor units/new services to be added after initial installation without any new cables • Greatly simplifies installation in MDU's (Multi dwelling units) • Enables subscription services like home security and diagnostics/maintenance of appliances. Davis Provis. at 5: The interface between the indoor units(s) and outdoor unit of DirecPC/DIRECTV/ DirecWay/Spaceway all could use this invention. … Wireless connections between ODU and IOU have been proposed before. As far as I know, these have been analog repeaters of the signals on the IDU/ODU cable, and performing esentially [sic] the same functions as the cable. Using a LAN allows multiple access, and greatly increased flexibility for future services via an industry standard method. Davis Provis. at 7: Current practice will often use what is called a "multiswitch" in an installation. This is a device that has one cable for each LNB on the ODU side, and one cable for each IDU satellite input on the IDU side. 	or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
12. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network.	Davis '055 discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network. *See* claim 10, *supra*. To the extent Davis '055 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Davis '055 alone or it would have been obvious to combine Davis '055 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Exhibit B4 – Davis '730 Invalidity Claim Chart

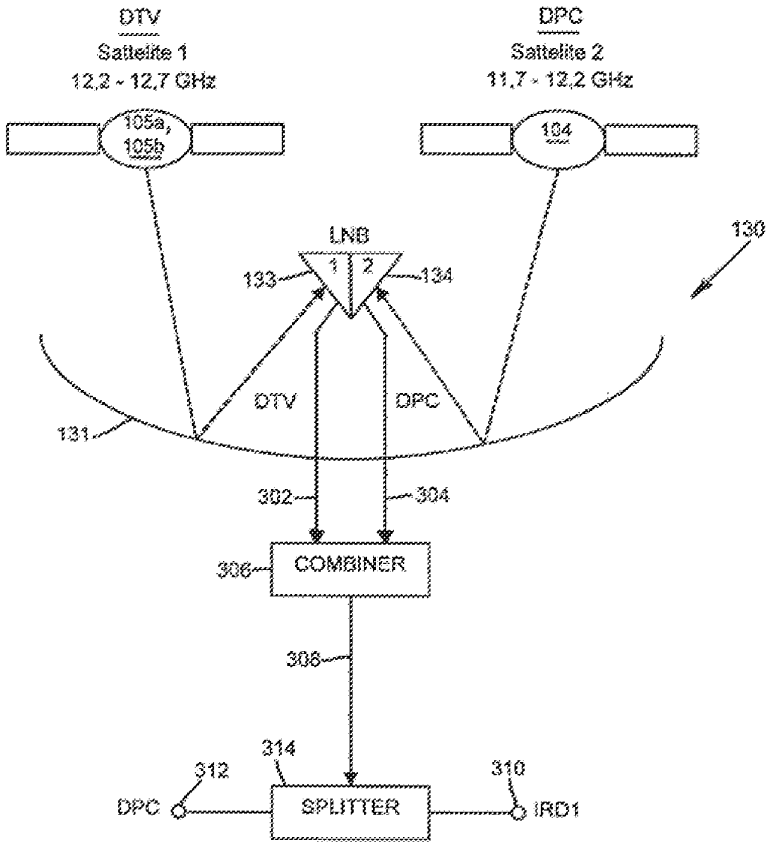
INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Davis '730

U.S. Patent No. 6,600,730 ("Davis '730") was filed on Aug. 20, 1998 and issued on July 29, 2003. Davis '730 therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(a) and/or (e). For the reasons listed below, Davis '730 invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

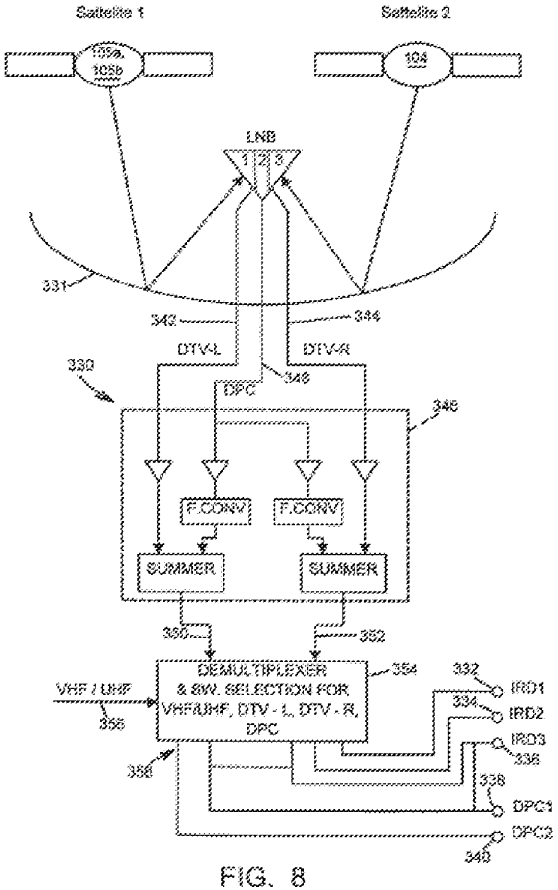
Asserted Claims	Davis '730
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Davis '730 discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*: Davis '730 at Abstract:

[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.

Asserted Claims	Davis '730
	A system for distributing separate multiple satellite communication services signals to receivers at a local earth site on a single cable line. A dual satellite antenna receives the signals from two separate satellites, each of which can correspond to a respective satellite communication service. The received satellite signals are processed into two separate frequency bands. A frequency converter using frequency division multiplexing converts at least one of the received frequency bands so as to position both of the frequency bands adjacent to each other. A summer receives the adjacent frequency bands and distributes them on a single cable line to receivers so that the receivers have access to the separate multiple satellite communication service signals on a single cable line. A demultiplexer coupled to the adjacent frequency bands from the summer enables the plurality of receivers at the output of the demultiplexer lines to obtain simultaneous access to both satellite communication services distributed over the single cable line to the receiver. Davis '730 at 1:10–14: The present invention relates in general to satellite receive earth stations and, more particularly, to a system for receiving satellite signals from separate and multiple satellites and distributing the signals received from the satellites on a single cable line. Davis '730 at 2:24–39: The present invention relates to a system for distributing satellite communication signals from separate multiple satellites on a single cable line. According to one aspect of the present invention, a dual satellite receiving antenna receives a first broadband signal at a first set of frequency bands corresponding to first satellite service signals, and a second broadband signal at a second set of frequency bands corresponding to second satellite service signals. A frequency converter using frequency division multiplexing receives and converts at least one of the sets of frequency bands to position the converted set of frequency bands adjacent to the other frequency band. A combiner receives the two adjacent frequency bands and distributes them on a single cable line to one or more



Asserted Claims	Davis '730
	receivers at the local site for access of the separate multiple satellite communication service signals by the receivers. Davis '730 at 2:40–56: According to another aspect of the present invention, a dual mode or two-channel LNB provides both the right-hand polarized and the left-hand polarized signals of a DTV satellite system signal to be provided via separate lines. A frequency converter, utilizing frequency division multiplexing frequency converts the signals from a second satellite system, such as, DPC with each of the separate DTV-left-hand polarization and right-hand polarization signals to provide two adjacent bands of frequency signals, each of which is separately combined in a respective summer unit and distributed on a single coaxial line. A demultiplexer and switch selection circuitry is provided for receiving the two separate lines from the respective summer units and provides a plurality of single cable output lines on which each coupled receiver may simultaneously access any of the received separate satellite signals from the multiple satellites and on a single cable line supplied to the respective receiver. Davis '730 at 3:43–54: Referring to FIG. 2, a preferred embodiment of the satellite receiver 130 as described in the aforementioned pending application Ser. No. 08/544,423 incorporated by reference herein, has a small aperture antenna 131, a siamese feedhorn 132, two low noise blocks (LNB) 133, 134, and a feedhorn support arm 135. The antenna 131 has a boresight line 137, from which the antenna 131 receives signals with maximum gain, and a beamwidth 138 along the boresight. Signals 144 within the beamwidth 138 are reflected and focused by the antenna 131 to a focal point 140. Siamese feedhorn 132 and LNBs 133, are mounted on a feedhorn support arm 135 and positioned at the focal point 140. Davis '730 at 4:62–5:13: As shown in FIG. 4, each of the respectively received separate satellite signals from the separate satellites are focused by antenna 131 at a focal point where there the LNBs 133,



Asserted Claims	Davis '730
	134 are located as previously described. An LNB is preferably comprised of an integrated low noise amplifier and a low noise frequency converter, and such devices are well-known to those skilled in the art. Reference may be made for instance to FIG. 5 where there is illustrated a representative LNB with an input 220 receiving signals from the antenna, and an output 229 coupling the intermediate frequency band to a receiver. Bandpass filters (BPF) 221, 222, 223 remove unwanted frequency signals while allowing desired signals to pass. Preferably, a field effect transistor (FET) amplifier 224, pre-amplifies the signal before it is mixed to the desired frequency. FET amplifier 224 is preferably a GaAs amplifier that provides a gain of 10 dB with a noise figure of 0.9 dB or less. Preferably, FET amplifier 224 provides a gain of 30 dB to 60 dB. Davis '730 at 5:14–23: Local oscillator (LO) 225 and Schottky diode 226 mix the signal to the desired frequency. The signal is then amplified by amplifier stage 227 before being sent but on a shielded coaxial line 229 to an indoor receiver. A voltage regulator 228 preferably regulates the voltage provided by the LNB to the indoor receiver and incorporates a voltage level switch control for selecting either the right-hand or left-hand polarized signals in response to a switch control signal from the indoor receiver in a manner well-known to those skilled in the art. Davis '730 at 5:24–32: The LNBs 133, 134 detect signals relayed from the feedhorn 132, convert the signals to an electrical current, amplify the signals, and downconvert the signals to a lower frequency. LNBs typically downconvert signals from the received satellite carrier frequencies to intermediate frequencies between 900 MHz and 2000 MHz. In the preferred embodiment, the LNB downconverts the satellite carrier signals to the intermediate frequency range of 950 to 1450 MHz. Davis '730 at 5:33–47:

Asserted Claims	Davis '730
	Typically, only the RHCP signals or the LHCP signals are converted down to the intermediate frequency, depending on which particular receiver channel a DTV user is viewing. That is, when the viewer selects a particular DTV channel, an appropriate voltage switch control level is supplied to the LNB in a known manner to control the local oscillator 225 so as to provide either the RHCP or the LHCP signals for return to the indoor receiver. However, in systems having a dual mode or two-channel LNB, as well-known to those skilled in the art, both RHCP LHCP signals may be individually shifted down to a 500 MHz portion of L-Band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, each like output line 229, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. Davis '730 at 5:48–61: Accordingly, in FIG. 4, the output on line 302 is a DTV-left-hand or right-hand polarized signal in the frequency range 950-1450 MHz. On an output line 304 from the LNB 134, there is provided the DPC satellite signals at the intermediate frequency range also of 950-1450 MHz. A combiner 306 provides frequency division multiplexing to the two input signals on lines 302, 304 and locates the band of frequencies together so that they are adjacent and consecutive, thereby enabling them to be placed on a single coaxial cable line 308 for distribution to respective IRD and DPC units at respective terminals 310, 312, each of which is connected to a respective single coaxial line ultimately connected through a splitter 314 to the single coaxial line 308. Davis '730 at 6:15–32: Reference may be made now to FIG. 8 wherein there is illustrated a local earth site distribution system 330 which enables each of the users at terminals 332, 334 . . . 340 to have access to both the left-hand as well as the right-hand DTV signals from satellites 105 a, 105 b, as well as having access to the DPC signals from satellite 104. In the embodiment 330 shown in FIG. 8, the receiving antenna 331 includes an LNB with three outputs. One of the LNB outputs is a downconverted intermediate frequency from satellite 105 a, 105 b representing the left-hand polarized signals in the range 950 MHz to 1450 MHz, and is

Asserted Claims	Davis '730
	labelled DTV-L and is supplied on output line 342. Similarly, output line 344 contains the downconverted right-hand polarized portion of the 950 MHz to 1450 MHz signals from satellites 105 a, 105 b and is indicated in FIG. 8 as DTVR. The third output line 346 of the LNB provides the downconverted intermediate frequencies received from satellite 104, and this output line is accordingly labelled DPC. Davis '730 at 6:33–50: The three LNB output lines 342, 344, 346 are coupled to a combiner 348 which includes frequency converters and summers for providing frequency division multiplexing of the input signals. Reference may be made to FIG. 7(c) wherein there is illustrated the results of the frequency division multiplexing supplied by combiner 348. In particular, it can be seen from FIG. 7(c) that the DTV left-hand and right-hand polarized signals are available in the frequency range 950 MHz to 1450 MHz, whereas all of the DPC signals have been frequency converted and positioned in the 1550 MHz to 2050 MHz frequency band. The DTV-left-hand polarized signals and the DPC vertical polarized signals are provided on combiner 348 output line 350. The DTV right-hand polarized signals and the DPC horizontally polarized signals are provided on combiner 348 output line 352. FIG. 7(b) shows an alternative distribution of the DTV and DPC signals using frequency division multiplexing. Davis '730 at 6:51–68: A demultiplexer 354 includes respective inputs for receiving output lines 350 and 352, and also an input line 356 containing VHF/UHF broadcast signals. Demultiplexer 354 includes output lines 358 each of which can supply any of the signals from input lines 350, 352 and 356 for coupling to the respective terminals 332, 334 . . . 340. For instance, the IRD 1 unit coupled to terminal 332 has access to all of the signals received from both of the separate satellites 105 a, 105 b as well as from satellite 104. Coupling of the selected signals is accomplished automatically in a well-known manner, such as by using voltage biased levels supplied from IRD 1 to a switch selector in the multiplexer 354 to accomplish the selection of the particular signal desired. This switch selection may be accomplished in a

Asserted Claims	Davis '730
	manner similar to that previously described with respect to existing LNBs. Demultiplexer 354 is a standard commercially available unit, such as Channelmaster model 63141FD, or similar available units such as. Davis '730 at Fig. 4:

9[a] a gateway in communication with the ODU and at least one set top box (STB);	Davis '730 discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Davis '730 at Abstract: A system for distributing separate multiple satellite communication services signals to receivers at a local earth site on a single cable line. A dual satellite antenna receives the signals from two separate satellites, each of which can correspond to a respective satellite communication service. The received satellite signals are processed into two separate frequency bands. A frequency converter using frequency division multiplexing converts at least one of the received frequency bands so as to position both of the frequency bands adjacent to each other. A summer receives the adjacent frequency bands and distributes them on a single cable line to receivers so that the receivers have access to the separate multiple satellite communication service signals on a single cable line. A demultiplexer coupled to the adjacent frequency bands from the summer enables the plurality of receivers at the output of the demultiplexer lines to obtain simultaneous access to both satellite communication services distributed over the single cable line to the receiver. Davis '730 at 5:48–61: Accordingly, in FIG. 4, the output on line 302 is a DTV-left-hand or right-hand polarized signal in the frequency range 950-1450 MHz. On an output line 304 from the LNB 134, there is provided the DPC satellite signals at the intermediate frequency range also of 950-1450 MHz. A combiner 306 provides frequency division multiplexing to the two input signals on lines 302, 304 and locates the band of frequencies together so that they are adjacent and consecutive, thereby enabling them to be placed on a single coaxial cable line 308 for distribution to respective IRD and DPC units at respective terminals 310, 312, each

Asserted Claims	Davis '730
	of which is connected to a respective single coaxial line ultimately connected through a splitter 314 to the single coaxial line 308. Davis '730 at 6:51–68: A demultiplexer 354 includes respective inputs for receiving output lines 350 and 352, and also an input line 356 containing VHF/UHF broadcast signals. Demultiplexer 354 includes output lines 358 each of which can supply any of the signals from input lines 350, 352 and 356 for coupling to the respective terminals 332, 334 . . . 340. For instance, the IRD 1 unit coupled to terminal 332 has access to all of the signals received from both of the separate satellites 105 a, 105 b as well as from satellite 104. Coupling of the selected signals is accomplished automatically in a well-known manner, such as by using voltage biased levels supplied from IRD 1 to a switch selector in the multiplexer 354 to accomplish the selection of the particular signal desired. This switch selection may be accomplished in a manner similar to that previously described with respect to existing LNBs. Demultiplexer 354 is a standard commercially available unit, such as Channelmaster model 63141FD, or similar available units such as. Davis '730 at Fig. 4:

9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information;	Davis '730 discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*: Davis '730 at Abstract: A system for distributing separate multiple satellite communication services signals to receivers at a local earth site on a single cable line. A dual satellite antenna receives the signals from two separate satellites, each of which can correspond to a respective satellite communication service. The received satellite signals are processed into two separate frequency bands. A frequency converter using frequency division multiplexing converts at least one of the received frequency bands so as to position both of the frequency bands adjacent to each other. A summer receives the adjacent frequency bands and distributes them on a single cable line to receivers so that the receivers have access to the separate multiple satellite communication service signals on a single cable line. A demultiplexer coupled to the adjacent frequency bands from the summer enables the plurality of receivers at the output of the demultiplexer lines to obtain simultaneous access to both satellite communication services distributed over the single cable line to the receiver. Davis '730 at 2:40–56: According to another aspect of the present invention, a dual mode or two-channel LNB provides both the right-hand polarized and the left-hand polarized signals of a DTV satellite system signal to be provided via separate lines. A frequency converter, utilizing frequency division multiplexing frequency converts the signals from a second satellite

Asserted Claims	Davis '730
	system, such as, DPC with each of the separate DTV-left-hand polarization and right-hand polarization signals to provide two adjacent bands of frequency signals, each of which is separately combined in a respective summer unit and distributed on a single coaxial line. A demultiplexer and switch selection circuitry is provided for receiving the two separate lines from the respective summer units and provides a plurality of single cable output lines on which each coupled receiver may simultaneously access any of the received separate satellite signals from the multiple satellites and on a single cable line supplied to the respective receiver. Davis '730 at 5:14–23: Local oscillator (LO) 225 and Schottky diode 226 mix the signal to the desired frequency. The signal is then amplified by amplifier stage 227 before being sent but on a shielded coaxial line 229 to an indoor receiver. A voltage regulator 228 preferably regulates the voltage provided by the LNB to the indoor receiver and incorporates a voltage level switch control for selecting either the right-hand or left-hand polarized signals in response to a switch control signal from the indoor receiver in a manner well-known to those skilled in the art. Davis '730 at 5:33–47: Typically, only the RHCP signals or the LHCP signals are converted down to the intermediate frequency, depending on which particular receiver channel a DTV user is viewing. That is, when the viewer selects a particular DTV channel, an appropriate voltage switch control level is supplied to the LNB in a known manner to control the local oscillator 225 so as to provide either the RHCP or the LHCP signals for return to the indoor receiver. However, in systems having a dual mode or two-channel LNB, as well-known to those skilled in the art, both RHCP LHCP signals may be individually shifted down to a 500 MHz portion of L-Band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, each like output line 229, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit.

Asserted Claims	Davis '730
	Davis '730 at 5:48–61: Accordingly, in FIG. 4, the output on line 302 is a DTV-left-hand or right-hand polarized signal in the frequency range 950-1450 MHz. On an output line 304 from the LNB 134, there is provided the DPC satellite signals at the intermediate frequency range also of 950-1450 MHz. A combiner 306 provides frequency division multiplexing to the two input signals on lines 302, 304 and locates the band of frequencies together so that they are adjacent and consecutive, thereby enabling them to be placed on a single coaxial cable line 308 for distribution to respective IRD and DPC units at respective terminals 310, 312, each of which is connected to a respective single coaxial line ultimately connected through a splitter 314 to the single coaxial line 308. Davis '730 at 6:51–68: A demultiplexer 354 includes respective inputs for receiving output lines 350 and 352, and also an input line 356 containing VHF/UHF broadcast signals. Demultiplexer 354 includes output lines 358 each of which can supply any of the signals from input lines 350, 352 and 356 for coupling to the respective terminals 332, 334 . . . 340. For instance, the IRD 1 unit coupled to terminal 332 has access to all of the signals received from both of the separate satellites 105 a, 105 b as well as from satellite 104. Coupling of the selected signals is accomplished automatically in a well-known manner, such as by using voltage biased levels supplied from IRD 1 to a switch selector in the multiplexer 354 to accomplish the selection of the particular signal desired. This switch selection may be accomplished in a manner similar to that previously described with respect to existing LNBs. Demultiplexer 354 is a standard commercially available unit, such as Channelmaster model 63141FD, or similar available units such as. Davis '730 at Fig. 4:

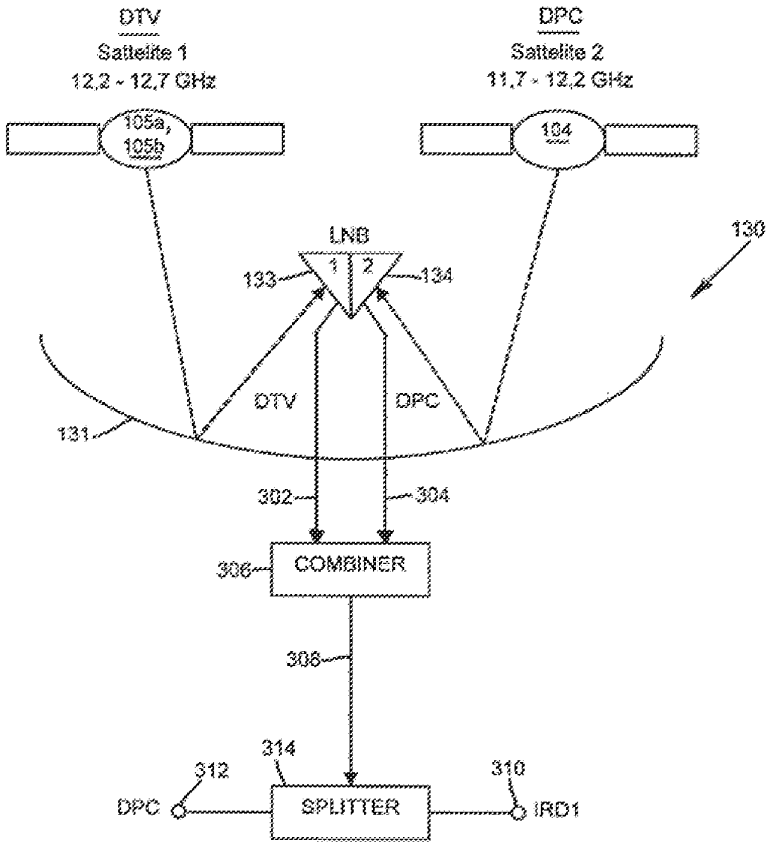
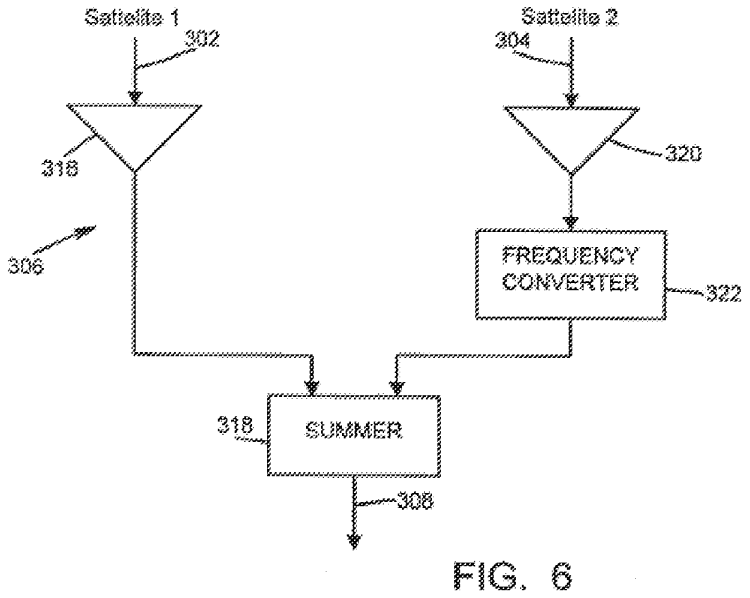
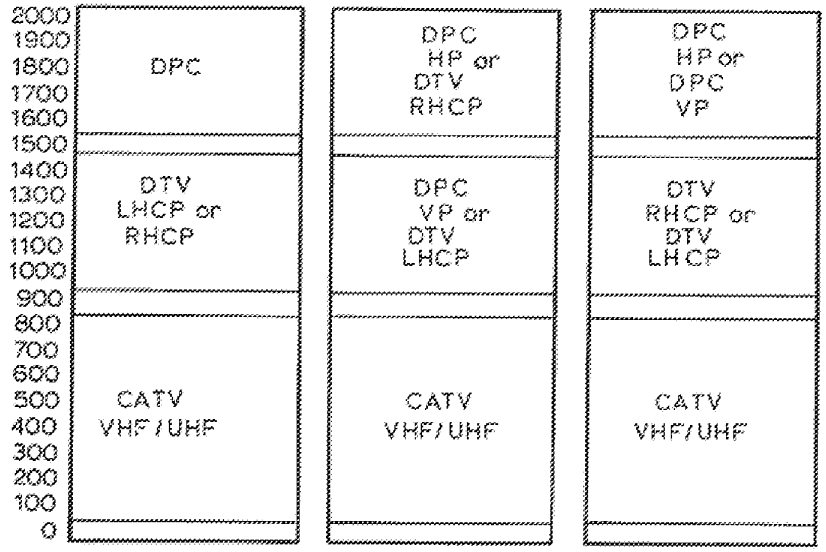
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Davis '730 discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*: Davis '730 at Abstract: A system for distributing separate multiple satellite communication services signals to receivers at a local earth site on a single cable line. A dual satellite antenna receives the signals from two separate satellites, each of which can correspond to a respective satellite communication service. The received satellite signals are processed into two separate frequency bands. A frequency converter using frequency division multiplexing converts at least one of the received frequency bands so as to position both of the frequency bands adjacent to each other. A summer receives the adjacent frequency bands and distributes them on a single cable line to receivers so that the receivers have access to the separate multiple satellite communication service signals on a single cable line. A demultiplexer coupled to the adjacent frequency bands from the summer enables the plurality of receivers at the output of the demultiplexer lines to obtain simultaneous access to both satellite communication services distributed over the single cable line to the receiver. Davis '730 at 2:24–39: The present invention relates to a system for distributing satellite communication signals from separate multiple satellites on a single cable line. According to one aspect of the present invention, a dual satellite receiving antenna receives a first broadband signal at a first set of frequency bands corresponding to first satellite service signals, and a second broadband signal at a second set of frequency bands corresponding to second satellite service signals. A frequency converter using frequency division multiplexing receives and



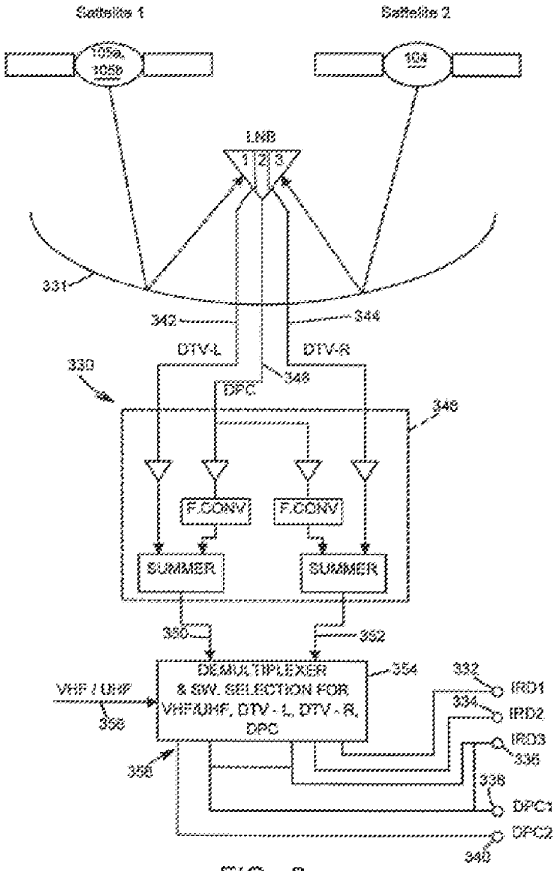
Asserted Claims	Davis '730
	converts at least one of the sets of frequency bands to position the converted set of frequency bands adjacent to the other frequency band. A combiner receives the two adjacent frequency bands and distributes them on a single cable line to one or more receivers at the local site for access of the separate multiple satellite communication service signals by the receivers. Davis '730 at 2:40–56: According to another aspect of the present invention, a dual mode or two-channel LNB provides both the right-hand polarized and the left-hand polarized signals of a DTV satellite system signal to be provided via separate lines. A frequency converter, utilizing frequency division multiplexing frequency converts the signals from a second satellite system, such as, DPC with each of the separate DTV-left-hand polarization and right-hand polarization signals to provide two adjacent bands of frequency signals, each of which is separately combined in a respective summer unit and distributed on a single coaxial line. A demultiplexer and switch selection circuitry is provided for receiving the two separate lines from the respective summer units and provides a plurality of single cable output lines on which each coupled receiver may simultaneously access any of the received separate satellite signals from the multiple satellites and on a single cable line supplied to the respective receiver. Davis '730 at 3:27–42: Preferably, uplink transmitter 102 modulates a digital signal onto the assigned frequency carriers for uplink to satellites 105 a, 105 b. Satellites 105 a, 105 b translate the uplink carriers to the assigned Ku2-band downlink frequency carriers, (over 12 GHz), for downlink to the satellite receiver 130. The satellites 105 a, 105 b ordinarily transmit carrier signals with alternating left-hand circularly polarized (LHCP) and right-hand circularly polarized (RHCP) signals. Preferably, satellites 105 a, 105 are high-power satellites that transmit downlink signals in a focused beam pattern 108. Similarly, the uplink transmitter 101 uplinks signals to satellite 104. The satellite 104 translates the carrier signals to the assigned C-band or Ku-band downlink frequencies for subsequent demodulation and



Asserted Claims	Davis '730
	downlink to the satellite receiver 130. The satellite 104, ordinarily transmits carriers with alternating vertical and horizontal polarity. Davis '730 at 4:62–5:13: As shown in FIG. 4, each of the respectively received separate satellite signals from the separate satellites are focused by antenna 131 at a focal point where there the LNBs 133, 134 are located as previously described. An LNB is preferably comprised of an integrated low noise amplifier and a low noise frequency converter, and such devices are well-known to those skilled in the art. Reference may be made for instance to FIG. 5 where there is illustrated a representative LNB with an input 220 receiving signals from the antenna, and an output 229 coupling the intermediate frequency band to a receiver. Bandpass filters (BPF) 221, 222, 223 remove unwanted frequency signals while allowing desired signals to pass. Preferably, a field effect transistor (FET) amplifier 224, pre-amplifies the signal before it is mixed to the desired frequency. FET amplifier 224 is preferably a GaAs amplifier that provides a gain of 10 dB with a noise figure of 0.9 dB or less. Preferably, FET amplifier 224 provides a gain of 30 dB to 60 dB. Davis '730 at 5:14–23: Local oscillator (LO) 225 and Schottky diode 226 mix the signal to the desired frequency. The signal is then amplified by amplifier stage 227 before being sent but on a shielded coaxial line 229 to an indoor receiver. A voltage regulator 228 preferably regulates the voltage provided by the LNB to the indoor receiver and incorporates a voltage level switch control for selecting either the right-hand or left-hand polarized signals in response to a switch control signal from the indoor receiver in a manner well-known to those skilled in the art. Davis '730 at 5:24–32: The LNBs 133, 134 detect signals relayed from the feedhorn 132, convert the signals to an electrical current, amplify the signals, and downconvert the signals to a lower frequency. LNBs typically downconvert signals from the received satellite carrier frequencies to



Asserted Claims	Davis '730
	intermediate frequencies between 900 MHz and 2000 MHz. In the preferred embodiment, the LNB downconverts the satellite carrier signals to the intermediate frequency range of 950 to 1450 MHz. Davis '730 at 5:33–47: Typically, only the RHCP signals or the LHCP signals are converted down to the intermediate frequency, depending on which particular receiver channel a DTV user is viewing. That is, when the viewer selects a particular DTV channel, an appropriate voltage switch control level is supplied to the LNB in a known manner to control the local oscillator 225 so as to provide either the RHCP or the LHCP signals for return to the indoor receiver. However, in systems having a dual mode or two-channel LNB, as well-known to those skilled in the art, both RHCP LHCP signals may be individually shifted down to a 500 MHz portion of L-Band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, each like output line 229, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. Davis '730 at 5:48–61: Accordingly, in FIG. 4, the output on line 302 is a DTV-left-hand or right-hand polarized signal in the frequency range 950-1450 MHz. On an output line 304 from the LNB 134, there is provided the DPC satellite signals at the intermediate frequency range also of 950-1450 MHz. A combiner 306 provides frequency division multiplexing to the two input signals on lines 302, 304 and locates the band of frequencies together so that they are adjacent and consecutive, thereby enabling them to be placed on a single coaxial cable line 308 for distribution to respective IRD and DPC units at respective terminals 310, 312, each of which is connected to a respective single coaxial line ultimately connected through a splitter 314 to the single coaxial line 308. Davis '730 at 5:62–6:4: Referring to FIG. 6, there is illustrated the details of the combiner 306. Input line 302 containing the DTV, either left-hand or right-hand polarized signals is coupled to a buffer



Asserted Claims	Davis '730
	amplifier 316 and then supplied to a summer 318. Input line 304 containing the DPC frequency band also at 950-1450 MHz is coupled to a buffer amplifier 320 and thereafter coupled to a frequency converter 322 for upconverting the 95014 1450 MHz band to a band between about 1550-2050 MHz. Davis '730 at 6:5–14: Reference may be made to FIG. 7(a) wherein the frequency distribution at the output of summer 318 on output line 308 is illustrated for convenience. As can be seen from this frequency distribution chart, the DPC band of frequencies has been located adjacent and consecutive with the DTV left-hand or right-hand polarized signals. For purposes of illustration, the lower band of frequencies between about 50 MHz to 850 MHz is illustrated as reserved for CATV or VHF/UHF cable signals which provide VHF/UHF broadcast channel signals in a known manner. Davis '730 at 6:15–32: Reference may be made now to FIG. 8 wherein there is illustrated a local earth site distribution system 330 which enables each of the users at terminals 332, 334 . . . 340 to have access to both the left-hand as well as the right-hand DTV signals from satellites 105 a, 105 b, as well as having access to the DPC signals from satellite 104. In the embodiment 330 shown in FIG. 8, the receiving antenna 331 includes an LNB with three outputs. One of the LNB outputs is a downconverted intermediate frequency from satellite 105 a, 105 b representing the left-hand polarized signals in the range 950 MHz to 1450 MHz, and is labelled DTV-L and is supplied on output line 342. Similarly, output line 344 contains the downconverted right-hand polarized portion of the 950 MHz to 1450 MHz signals from satellites 105 a, 105 b and is indicated in FIG. 8 as DTVR. The third output line 346 of the LNB provides the downconverted intermediate frequencies received from satellite 104, and this output line is accordingly labelled DPC. Davis '730 at 6:33–50:

Asserted Claims	Davis '730
	The three LNB output lines 342, 344, 346 are coupled to a combiner 348 which includes frequency converters and summers for providing frequency division multiplexing of the input signals. Reference may be made to FIG. 7(c) wherein there is illustrated the results of the frequency division multiplexing supplied by combiner 348. In particular, it can be seen from FIG. 7(c) that the DTV left-hand and right-hand polarized signals are available in the frequency range 950 MHz to 1450 MHz, whereas all of the DPC signals have been frequency converted and positioned in the 1550 MHz to 2050 MHz frequency band. The DTV-left-hand polarized signals and the DPC vertical polarized signals are provided on combiner 348 output line 350. The DTV right-hand polarized signals and the DPC horizontally polarized signals are provided on combiner 348 output line 352. FIG. 7(b) shows an alternative distribution of the DTV and DPC signals using frequency division multiplexing. Davis '730 at Fig. 4:

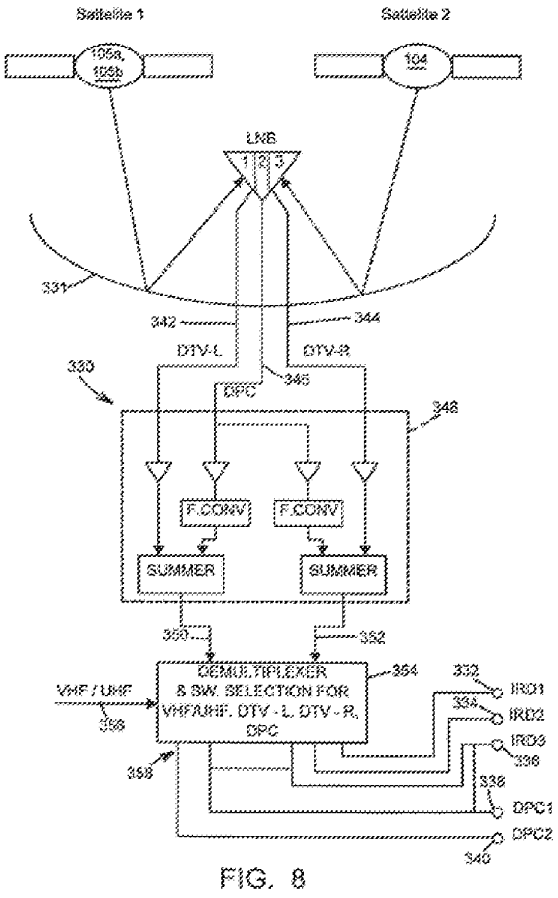
9[d] a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal;	Davis '730 discloses, explicitly and/or inherently, a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal. *See, e.g.*: Davis '730 at Abstract: A system for distributing separate multiple satellite communication services signals to receivers at a local earth site on a single cable line. A dual satellite antenna receives the signals from two separate satellites, each of which can correspond to a respective satellite communication service. The received satellite signals are processed into two separate frequency bands. A frequency converter using frequency division multiplexing converts at least one of the received frequency bands so as to position both of the frequency bands adjacent to each other. A summer receives the adjacent frequency bands and distributes them on a single cable line to receivers so that the receivers have access to the separate multiple satellite communication service signals on a single cable line. A demultiplexer coupled to the adjacent frequency bands from the summer enables the plurality of receivers at the output of the demultiplexer lines to obtain simultaneous access to both satellite communication services distributed over the single cable line to the receiver. Davis '730 at 2:24–39: The present invention relates to a system for distributing satellite communication signals from separate multiple satellites on a single cable line. According to one aspect of the present invention, a dual satellite receiving antenna receives a first broadband signal at a first set of frequency bands corresponding to first satellite service signals, and a second broadband signal at a second set of frequency bands corresponding to second satellite service signals. A frequency converter using frequency division multiplexing receives and



Asserted Claims	Davis '730
	converts at least one of the sets of frequency bands to position the converted set of frequency bands adjacent to the other frequency band. A combiner receives the two adjacent frequency bands and distributes them on a single cable line to one or more receivers at the local site for access of the separate multiple satellite communication service signals by the receivers. Davis '730 at 2:40–56: According to another aspect of the present invention, a dual mode or two-channel LNB provides both the right-hand polarized and the left-hand polarized signals of a DTV satellite system signal to be provided via separate lines. A frequency converter, utilizing frequency division multiplexing frequency converts the signals from a second satellite system, such as, DPC with each of the separate DTV-left-hand polarization and right-hand polarization signals to provide two adjacent bands of frequency signals, each of which is separately combined in a respective summer unit and distributed on a single coaxial line. A demultiplexer and switch selection circuitry is provided for receiving the two separate lines from the respective summer units and provides a plurality of single cable output lines on which each coupled receiver may simultaneously access any of the received separate satellite signals from the multiple satellites and on a single cable line supplied to the respective receiver. Davis '730 at 5:48–61: Accordingly, in FIG. 4, the output on line 302 is a DTV-left-hand or right-hand polarized signal in the frequency range 950-1450 MHz. On an output line 304 from the LNB 134, there is provided the DPC satellite signals at the intermediate frequency range also of 950-1450 MHz. A combiner 306 provides frequency division multiplexing to the two input signals on lines 302, 304 and locates the band of frequencies together so that they are adjacent and consecutive, thereby enabling them to be placed on a single coaxial cable line 308 for distribution to respective IRD and DPC units at respective terminals 310, 312, each

Asserted Claims	Davis '730
	of which is connected to a respective single coaxial line ultimately connected through a splitter 314 to the single coaxial line 308. Davis '730 at 5:62–6:4: Referring to FIG. 6, there is illustrated the details of the combiner 306. Input line 302 containing the DTV, either left-hand or right-hand polarized signals is coupled to a buffer amplifier 316 and then supplied to a summer 318. Input line 304 containing the DPC frequency band also at 950-1450 MHz is coupled to a buffer amplifier 320 and thereafter coupled to a frequency converter 322 for upconverting the 95014 1450 MHz band to a band between about 1550-2050 MHz. Davis '730 at 6:5–14: Reference may be made to FIG. 7(a) wherein the frequency distribution at the output of summer 318 on output line 308 is illustrated for convenience. As can be seen from this frequency distribution chart, the DPC band of frequencies has been located adjacent and consecutive with the DTV left-hand or right-hand polarized signals. For purposes of illustration, the lower band of frequencies between about 50 MHz to 850 MHz is illustrated as reserved for CATV or VHF/UHF cable signals which provide VHF/UHF broadcast channel signals in a known manner. Davis '730 at 6:33–50: The three LNB output lines 342, 344, 346 are coupled to a combiner 348 which includes frequency converters and summers for providing frequency division multiplexing of the input signals. Reference may be made to FIG. 7(c) wherein there is illustrated the results of the frequency division multiplexing supplied by combiner 348. In particular, it can be seen from FIG. 7(c) that the DTV left-hand and right-hand polarized signals are available in the frequency range 950 MHz to 1450 MHz, whereas all of the DPC signals have been frequency converted and positioned in the 1550 MHz to 2050 MHz frequency band. The DTV-left-hand polarized signals and the DPC vertical polarized signals are provided on combiner 348 output line 350. The DTV right-hand polarized signals and the DPC

Asserted Claims	Davis '730
	horizontally polarized signals are provided on combiner 348 output line 352. FIG. 7(b) shows an alternative distribution of the DTV and DPC signals using frequency division multiplexing. Davis '730 at Fig. 4:

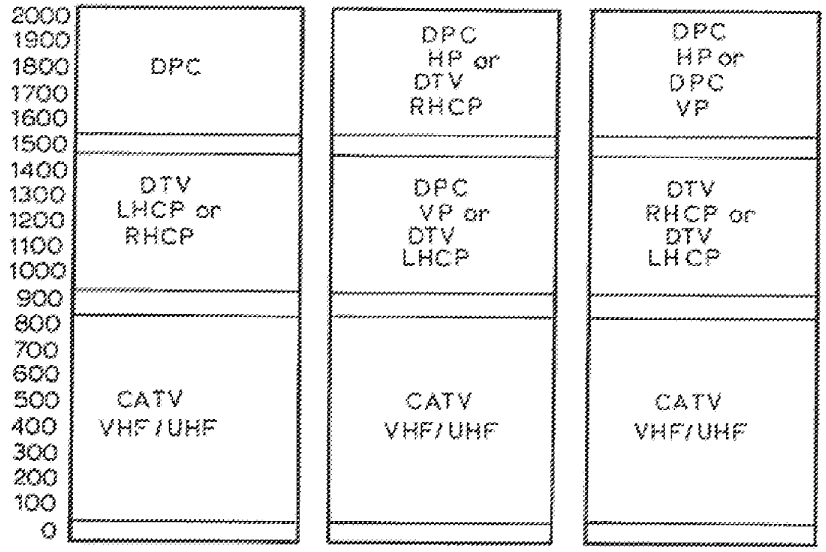
	 FIG. 8 To the extent Davis '730 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Davis '730 alone or it would have been obvious to combine Davis '730 with one



Asserted Claims	Davis '730
	or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[e] wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs.	Davis '730 discloses, explicitly and/or inherently, wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs. *See, e.g.*: Davis '730 at Abstract: A system for distributing separate multiple satellite communication services signals to receivers at a local earth site on a single cable line. A dual satellite antenna receives the signals from two separate satellites, each of which can correspond to a respective satellite communication service. The received satellite signals are processed into two separate frequency bands. A frequency converter using frequency division multiplexing converts at least one of the received frequency bands so as to position both of the frequency bands adjacent to each other. A summer receives the adjacent frequency bands and distributes them on a single cable line to receivers so that the receivers have access to the separate multiple satellite communication service signals on a single cable line. A demultiplexer coupled to the adjacent frequency bands from the summer enables the plurality of receivers at the output of the demultiplexer lines to obtain simultaneous access to both satellite communication services distributed over the single cable line to the receiver. Davis '730 at 5:48–61: Accordingly, in FIG. 4, the output on line 302 is a DTV-left-hand or right-hand polarized signal in the frequency range 950-1450 MHz. On an output line 304 from the LNB 134, there is provided the DPC satellite signals at the intermediate frequency range also of 950-1450 MHz. A combiner 306 provides frequency division multiplexing to the two input

Asserted Claims	Davis '730
	signals on lines 302, 304 and locates the band of frequencies together so that they are adjacent and consecutive, thereby enabling them to be placed on a single coaxial cable line 308 for distribution to respective IRD and DPC units at respective terminals 310, 312, each of which is connected to a respective single coaxial line ultimately connected through a splitter 314 to the single coaxial line 308. Davis '730 at 6:51–68: A demultiplexer 354 includes respective inputs for receiving output lines 350 and 352, and also an input line 356 containing VHF/UHF broadcast signals. Demultiplexer 354 includes output lines 358 each of which can supply any of the signals from input lines 350, 352 and 356 for coupling to the respective terminals 332, 334 . . . 340. For instance, the IRD 1 unit coupled to terminal 332 has access to all of the signals received from both of the separate satellites 105 a, 105 b as well as from satellite 104. Coupling of the selected signals is accomplished automatically in a well-known manner, such as by using voltage biased levels supplied from IRD 1 to a switch selector in the multiplexer 354 to accomplish the selection of the particular signal desired. This switch selection may be accomplished in a manner similar to that previously described with respect to existing LNBs. Demultiplexer 354 is a standard commercially available unit, such as Channelmaster model 6314IFD, or similar available units such as. Davis '730 at Fig. 4:

	or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
10. The signal distribution system of claim 9 wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output.	Davis '730 discloses, explicitly and/or inherently, wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output. *See* claim 9, *supra*. *See, e.g.*: Davis '730 at 6:5–14: Reference may be made to FIG. 7(a) wherein the frequency distribution at the output of summer 318 on output line 308 is illustrated for convenience. As can be seen from this frequency distribution chart, the DPC band of frequencies has been located adjacent and consecutive with the DTV left-hand or right-hand polarized signals. For purposes of illustration, the lower band of frequencies between about 50 MHz to 850 MHz is illustrated as reserved for CATV or VHF/UHF cable signals which provide VHF/UHF broadcast channel signals in a known manner. Davis '730 at 6:33–50: The three LNB output lines 342, 344, 346 are coupled to a combiner 348 which includes frequency converters and summers for providing frequency division multiplexing of the input signals. Reference may be made to FIG. 7(c) wherein there is illustrated the results of the frequency division multiplexing supplied by combiner 348. In particular, it can be seen from FIG. 7(c) that the DTV left-hand and right-hand polarized signals are available in the frequency range 950 MHz to 1450 MHz, whereas all of the DPC signals have been frequency converted and positioned in the 1550 MHz to 2050 MHz frequency band. The DTV-left-hand polarized signals and the DPC vertical polarized signals are provided on combiner 348 output line 350. The DTV right-hand polarized signals and the DPC

Asserted Claims	Davis '730
	horizontally polarized signals are provided on combiner 348 output line 352. FIG. 7(b) shows an alternative distribution of the DTV and DPC signals using frequency division multiplexing. Davis '730 at Fig. 7:  FIG. 7A FIG. 7B FIG. 7C To the extent Davis '730 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Davis '730 alone or it would have been obvious to combine Davis '730 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Asserted Claims	Davis '730
11. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network.	Davis '730 discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network. *See* claim 10, *supra*. *See, e.g.*: Davis '730 at 6:5–14: Reference may be made to FIG. 7(a) wherein the frequency distribution at the output of summer 318 on output line 308 is illustrated for convenience. As can be seen from this frequency distribution chart, the DPC band of frequencies has been located adjacent and consecutive with the DTV left-hand or right-hand polarized signals. For purposes of illustration, the lower band of frequencies between about 50 MHz to 850 MHz is illustrated as reserved for CATV or VHF/UHF cable signals which provide VHF/UHF broadcast channel signals in a known manner. Davis '730 at 6:33–50: The three LNB output lines 342, 344, 346 are coupled to a combiner 348 which includes frequency converters and summers for providing frequency division multiplexing of the input signals. Reference may be made to FIG. 7(c) wherein there is illustrated the results of the frequency division multiplexing supplied by combiner 348. In particular, it can be seen from FIG. 7(c) that the DTV left-hand and right-hand polarized signals are available in the frequency range 950 MHz to 1450 MHz, whereas all of the DPC signals have been frequency converted and positioned in the 1550 MHz to 2050 MHz frequency band. The DTV-left-hand polarized signals and the DPC vertical polarized signals are provided on combiner 348 output line 350. The DTV right-hand polarized signals and the DPC horizontally polarized signals are provided on combiner 348 output line 352. FIG. 7(b)

Asserted Claims	Davis '730
	shows an alternative distribution of the DTV and DPC signals using frequency division multiplexing. Exhibit B5 – Fisk Invalidity Claim Chart

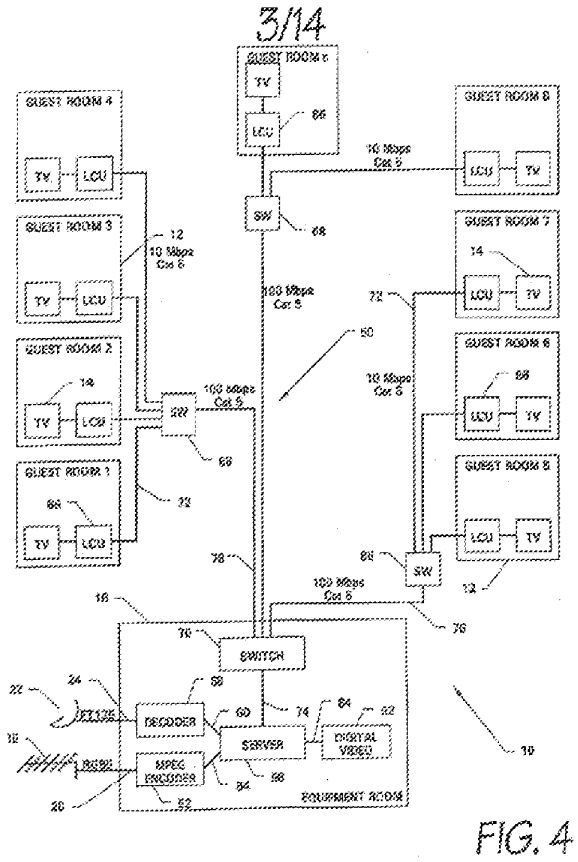
INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Fisk

International Publication No. WO 02/065771 A1 ("Fisk") has an international filing date of February 9, 2001, and was published on August 22, 2002. Fisk was published in the English language and designates the United States. Fisk therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(e). For the reasons listed below, Fisk invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Fisk
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Fisk discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*: Fisk at 10:23-11:5:



[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.

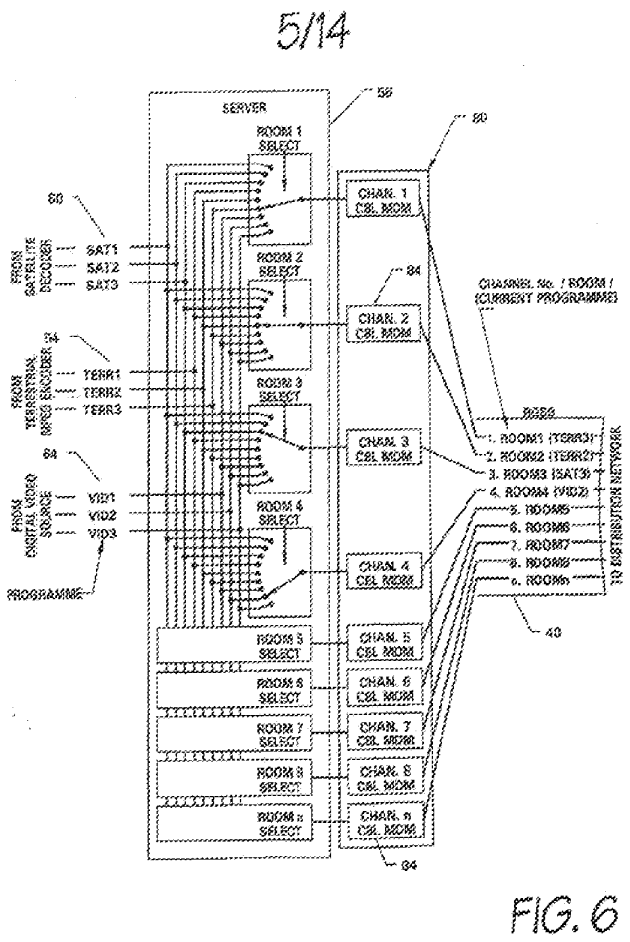
Asserted Claims	Fisk
	Additionally or alternatively, the receiving means may include a satellite dish for receiving scrambled and multiplexed satellite analogue television signals for a plurality of programmes, and means for descrambling and demultiplexing the signal for at least one of the programmes (for example a processor). However, since many satellite distributors use proprietary software and hardware (their "set top box") to ensure that programmes are only received by registered subscribers, the receiving means may alternatively or additionally include a satellite receiver, for instance a satellite dish, for receiving scrambled and multiplexed satellite analogue television signals for a plurality of programmes, means for descrambling and demultiplexing the signal for at least one of the programmes to produce an intermediate signal, means for modulating an RF signal with the intermediate signal, and means for demodulating the modulated RF signal. The descrambling, demultiplexing and modulating may therefore be provided by a conventional set top box. Fisk at 41:7-24: Referring also to FIGS. 19 to 23, the server may include the following components: television and radio cards 180,182,184,188 that receive analogue RF and satellite signals and convert them to digital signals in MPEG-2 format, television and radio cards 190 that receive digital signals in MPEG-2 format; playout cards 186 that multicast an MPEG-2 or MP3 file over the hotel network; and the software for the server 56, e.g. the channel manager 178, streaming components, etc. The server 56 may, for example, be presented as an 8 unit rack for mounting in a "19 inch" cabinet. Inside the cabinet there are a motherboard (e.g. Intel 700 MHz processor, 256 MB RAM, and 18 GB disk), a PCI bus 191 with 24 slots for the media cards, a 100 Mbps network card 238, power supply and fan. The server uses a DHCP client to request IP addresses for each card installed, and an SNMP client that will report any change in the status of the cards to an SNMP server in the channel controller. Each media card 180-190 installed in the server 56 is connected to the IGMP switch 70 by a Category 5 fly lead 193 from the RJ45 port 192 on the card to a port on the Switch 70. If more than one server 56 is provided, each server 56 is connected to a hub, so they can communicate with other devices on the network. As already described, the switch 70 is connected to the network 38,50 via its up-link port. The switch supports IGMP

Asserted Claims	Fisk
	and runs at 100 Mbps. The number of ports on the switch 70 and the number of Switches will depend on each installation. Fisk at FIG. 6:  To the extent Fisk does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Fisk alone or it would have been obvious to combine Fisk with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[a] a gateway in communication with the ODU and at least one set top box (STB);	Fisk discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Fisk at Abstract: A system for distributing television/video signals to different locations comprises a server capable of providing digital television/video signals for a plurality of programmes, a plurality of receivers each at a respective one of said locations, and a network connecting the server to the receivers, each receiver being operable to select a required one of the programmes and to communicate the selection to the 9 server, the server being responsive to such a selection to transmit the digital television/video signal for the selected programme over the network addressed to the receiver that selected that programme, and

Asserted Claims	Fisk
	each receiver being responsive to the digital television/video signal that is addressed to that receiver So that point-to-point communication is established from the server to that receiver. Fisk at 4:1-11: Another aspect of the invention provides a receiver for use in a system for distributing television/video signals to different locations, the system comprising a server capable of providing digital television/video signals for a plurality of programmes, and the receiver comprising means for enabling connection to the server by means of a network (for example, a connector, for instance a telephone or coaxial connector), means for Selecting a required one of the programmes (for example a keypad), and means for com municating the selection to the server (for example, a transmitter), the receiver being responsive to a digital television/video signal that is transmitted by the server over the network and addressed to that receiver so that point-to-point communication is established from the server to the receiver, and receiver is tuned to a given channel. Fisk at 4:20-27: Another aspect of the invention provides a receiver for use in a system for distributing television/video signals to different locations, the system comprising a server capable of providing digital television/video signals for a plurality of programmes, the receiver comprising a connection to the server via a network, a selector for selecting a required one of the programmes, and a transmitter for communicating the selection to the server, the receiver being responsive to a digital television/video signal that is transmitted by the server over the network and addressed to that receiver so that point-to-point communication is established from the server to that receiver. Fisk at 22:9-27: In order to deal with these problems and disadvantages, the embodiment of the invention that will now be described with reference to FIG. 4 uses a switched point to-point digital

Asserted Claims	Fisk
	distribution network 50 employing an internet protocol (IP) and in particular the user datagram protocol (UDP/IP). In the equipment room 16, the downlead 20 from the terrestrial television aerial 18 feeds a receiver and MPEG encoder 52 which provides digital MPEG video streams 54 for the received terrestrial television programmes to a server 56 (although one server 56 has been shown in the drawing, several such servers may be employed). Also, the downlead 24 from the satellite dish 22 feeds a decoder/descrambler 58 which provides digital MPEG video streams 60 for the received satellite television programmes to the server 56. Furthermore, the video replay equipment 62 has a digital output and provides digital MPEG video streams 64 for the video programmes to the server 56. The server 56 selects which of the video streams is to be transmitted to which room 12, and places the selected video streams on the digital network 50 using UDP/IP, or TCP/IP, each addressed to the selected room 12. In each room 12, the television 14 is connected to the network 50 by a local control unit (LCU) 66 that receives the video stream addressed to that room 12, decodes it, and supplies the resulting analogue video and audio signals to the television 14. Each LCU 66 is also operable to send requests over the network 38 to the server 56, for example to change the television/video channel supplied to that LCU 66. Fisk at Fig. 4:

Asserted Claims	Fisk
	 FIG. 4 To the extent Fisk does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Fisk alone or it would have been obvious to combine Fisk with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.



Asserted Claims	Fisk
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information;	Fisk discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*: Fisk at Abstract: A system for distributing television/video signals to different locations comprises a server capable of providing digital television/video signals for a plurality of programmes, a plurality of receivers each at a respective one of said locations, and a network connecting the server to the receivers, each receiver being operable to select a required one of the programmes and to communicate the selection to the 9 server, the server being responsive to such a selection to transmit the digital television/video signal for the selected programme over the network addressed to the receiver that selected that programme, and each receiver being responsive to the digital television/video signal that is addressed to that receiver So that point-to-point communication is established from the server to that receiver. Fisk at 4:1-11: Another aspect of the invention provides a receiver for use in a system for distributing television/video signals to different locations, the system comprising a server capable of providing digital television/video signals for a plurality of programmes, and the receiver comprising means for enabling connection to the server by means of a network (for example, a connector, for instance a telephone or coaxial connector), means for Selecting a required one of the programmes (for example a keypad), and means for com municating the selection to the server (for example, a transmitter), the receiver being responsive to a digital television/video signal that is transmitted by the server over the network and

Asserted Claims	Fisk
	addressed to that receiver so that point-to-point communication is established from the server to the receiver, and receiver is tuned to a given channel. Fisk at 10:23-11:5: Additionally or alternatively, the receiving means may include a satellite dish for receiving scrambled and multiplexed satellite analogue television signals for a plurality of programmes, and means for descrambling and demultiplexing the signal for at least one of the programmes (for example a processor). However, since many satellite distributors use proprietary software and hardware (their "set top box") to ensure that programmes are only received by registered subscribers, the receiving means may alternatively or additionally include a satellite receiver, for instance a satellite dish, for receiving scrambled and multiplexed satellite analogue television signals for a plurality of programmes, means for descrambling and demultiplexing the signal for at least one of the programmes to produce an intermediate signal, means for modulating an RF signal with the intermediate signal, and means for demodulating the modulated RF signal. The descrambling, demultiplexing and modulating may therefore be provided by a conventional set top box. Fisk at 13:29-14:5: The invention further provides a range of circuit boards for controlling a television set, each circuit board of the range comprising means for connection to a generic circuit board, each circuit board of the range comprising means (for example, a receiver) for receiving a generic control signal, based on control instructions received from a network and/or from a user interface, from the generic circuit board, and means (for example a processor) for converting the generic control signal into a specific control signal having a different format than the generic control signal, and means (for example a transmitter) for supplying the specific control signals to a control interface of the television set so as to control the television set in accordance with the control instructions. Fisk at 22:9-27:

Asserted Claims	Fisk
	In order to deal with these problems and disadvantages, the embodiment of the invention that will now be described with reference to FIG. 4 uses a switched point to-point digital distribution network 50 employing an internet protocol (IP) and in particular the user datagram protocol (UDP/IP). In the equipment room 16, the downlead 20 from the terrestrial television aerial 18 feeds a receiver and MPEG encoder 52 which provides digital MPEG video streams 54 for the received terrestrial television programmes to a server 56 (although one server 56 has been shown in the drawing, several such servers may be employed). Also, the downlead 24 from the satellite dish 22 feeds a decoder/descrambler 58 which provides digital MPEG video streams 60 for the received satellite television programmes to the server 56. Furthermore, the video replay equipment 62 has a digital output and provides digital MPEG video streams 64 for the video programmes to the server 56. The server 56 selects which of the video streams is to be transmitted to which room 12, and places the selected video streams on the digital network 50 using UDP/IP, or TCP/IP, each addressed to the selected room 12. In each room 12, the television 14 is connected to the network 50 by a local control unit (LCU) 66 that receives the video stream addressed to that room 12, decodes it, and supplies the resulting analogue video and audio signals to the television 14. Each LCU 66 is also operable to send requests over the network 38 to the server 56, for example to change the television/video channel supplied to that LCU 66. Fisk at 40:10-19: The server 56 comprises media capture, compression, and streaming functions and includes a media manager 174 that handles media-related events. The media manager 174 collects channel and schedule information from a configuration manager 176 and then passes messages to a specific channel manager 178. These messages detail actions that need to be taken; for example, loading an asset file, or streaming an asset on a particular card/channel. The configuration manager 176 holds a central repository of system wide information. This data is used to control many aspects of a particular installation. A subset of the configuration manager database holds information specific to the server 56. This identifies the various servers, the cards that are registered, the channels that have been assigned, the loaded media assets and the overall schedule.

Asserted Claims	Fisk
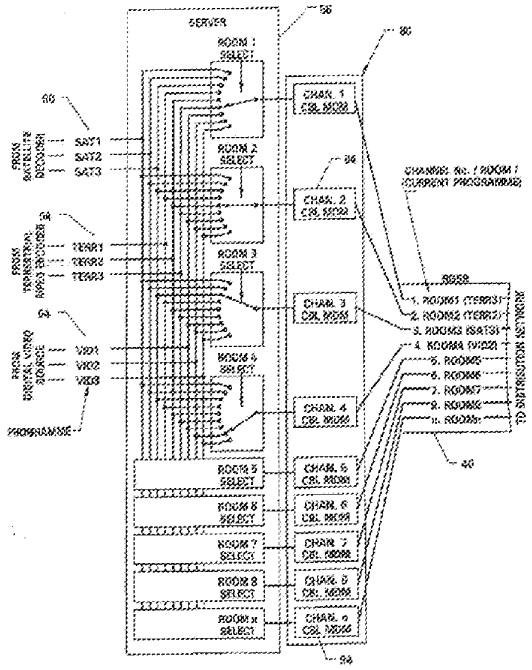
	 Fisk at 40:27-41:11:

Asserted Claims	Fisk
	The system supports the delivery of terrestrial television and radio, satellite television and pre-digitised media streams. Analogue streams, such as local television and radio channels, are captured and compressed prior to distribution. The delivery of analogue or digital television and radio requires efficient data capture and compression. This capability is available through hardware video and audio capture cards 180-184. These cards allow the capture of a variety of analogue and digital streams from television and radio, and the generation of digital streams in MPEG-2 format for video, or MP3 format for audio. However, these cards operate on one specific input channel, and so a single card is provided per channel. The MPEG-2 or MP3 stream that is generated by each card is routed directly to an address and port on the network. Referring also to Figures 19 to 23, the server may include the following components: television and radio cards 180,182,184,188 that receive analogue RF and satellite signals and convert them to digital signals in MPEG-2 format; television and radio cards 190 that receive digital signals in MPEG-2 format; playout cards 186 that 10 multicast an MPEG-2 or MP3 file over the hotel network; and the software for the server 56, e.g. the channel manager 178, streaming components, etc. Fisk at 42:6-43:12 & associated table: Turning now to the processing that is performed to convert the analogue radio frequency signals on which satellite channels are delivered to the hotel via satellite dish 22 into digital streams in MPEG-2 format, ideally the analogue satellite card 188 (FIG. 20) should receive signals directly from the satellite dish, de-scramble these and then select the appropriate channel, and convert the output to an MPEG stream. However, most of the satellite distributors use proprietary software and hardware to ensure that pro grammes are only received by registered subscribers. As a result, a set-top box 202 is required to receive, decrypt and transmit the required channel as a RF signal. The actual satellite card then becomes identical to the terrestrial TV card 182 (FIG. 19). With this approach a set-top box 202 is required for each satellite channel that is to be distributed within the hotel. One card 180,188 will be installed in the server 56 per satellite channel that the hotel wants to receive. The server 56 uses a DHCP client to request IP addresses for each card 180,188



Asserted Claims	Fisk
	installed. Each card 180,188 supports an SNMP client that reports any change in the status of the card to the SNMP server. The input port 194.204 of the first card is connected to the coaxial cable from the satellite dish. Additional cards can be added as required to the server 56. Where multiple cards are deployed a distribution amplifier is used to ensure that a consistent source signal strength is available to all cards. A hardware failure on one card will not affect the functioning of other cards. The listening frequency of the demodulator on each analogue satellite receiver card 180,188 will be under software control. The descrambling algorithms will also be under software control, if possible. The table below tracks the path of the stream sequentially through the analogue satellite receiver card 188, starting at the satellite dish 22 and terminating at the RJ45 output port 192 on the card 188.

Analogue Satellite Television Card 188			
Component	Path of Signal	Format	Notes
Satellite Receiver System	Satellite dish 22	Analogue, Scrambled, Multiplexed, Uncompressed	
	Coaxial cable 24	Analogue, Scrambled, Multiplexed, Uncompressed	
Satellite Receiver Card	Coaxial input port 204	Analogue, Scrambled, Multiplexed, Uncompressed	
	Descrambler 208	Analogue, Multiplexed, Uncompressed	
	Demultiplexer 210	Analogue, Uncompressed	The selected channel is under software control
	Analogue to digital converter 212	Digital, Uncompressed	
	MPEG-2 Compressor 214	Digital, MPEG-2	
	RJ45 output port 192	Digital, MPEG-2	An IP address is assigned to the port by a DHCP client on the server 56

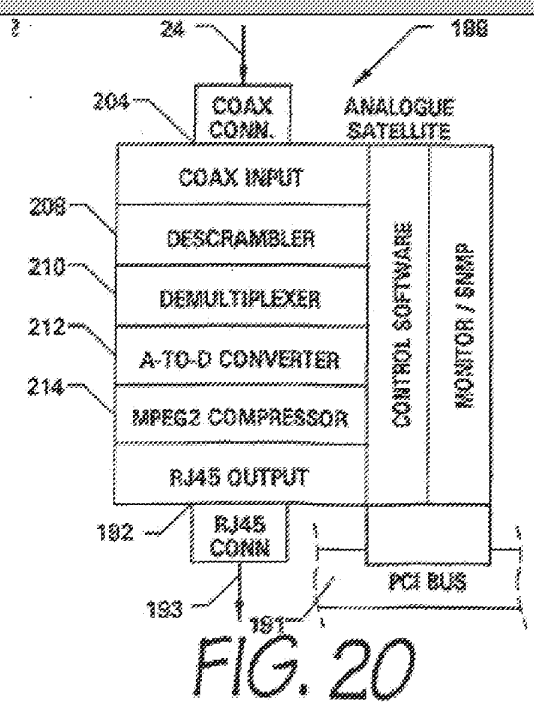
	 FIG. 20 Fisk at 44:10-15 & associated table on p. 45: In the case of the reception of digital satellite television, a card 190 (FIG.22) may be employed having a descrambler 230 and demultiplexer 232. The table below tracks the path of the stream sequentially through the digital satellite television card 190, starting at the satellite dish 22 and terminating at the RJ45 output port 192 on the card 190. To the extent Fisk does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Fisk alone or it would have been obvious to combine Fisk with one or more prior art

Asserted Claims	Fisk
	references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Fisk discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*: Fisk at Fig. 6:

Asserted Claims	Fisk
	5/14  FIG. 6 Fisk at 42:6-43:12 & associated table: Turning now to the processing that is performed to convert the analogue radio frequency signals on which satellite channels are delivered to the hotel via satellite dish 22 into digital streams in MPEG-2 format, ideally the analogue satellite card 188 (FIG. 20) should receive signals directly from the satellite dish, de-scramble these and then select the appropriate channel, and convert the output to an MPEG stream. However, most of the



Asserted Claims	Fisk
	satellite distributors use proprietary software and hardware to ensure that pro grammes are only received by registered subscribers. As a result, a set-top box 202 is required to receive, decrypt and transmit the required channel as a RF signal. The actual satellite card then becomes identical to the terrestrial TV card 182 (FIG. 19). With this approach a set-top box 202 is required for each satellite channel that is to be distributed within the hotel. One card 180,188 will be installed in the server 56 per satellite channel that the hotel wants to receive. The server 56 uses a DHCP client to request IP addresses for each card 180,188 installed. Each card 180,188 supports an SNMP client that reports any change in the status of the card to the SNMP server. The input port 194.204 of the first card is connected to the coaxial cable from the satellite dish. Additional cards can be added as required to the server 56. Where multiple cards are deployed a distribution amplifier is used to ensure that a consistent source signal strength is available to all cards. A hardware failure on one card will not affect the functioning of other cards. The listening frequency of the demodulator on each analogue satellite receiver card 180,188 will be under software control. The descrambling algorithms will also be under software control, if possible. The table below tracks the path of the stream sequentially through the analogue satellite receiver card 188, starting at the satellite dish 22 and terminating at the RJ45 output port 192 on the card 188.

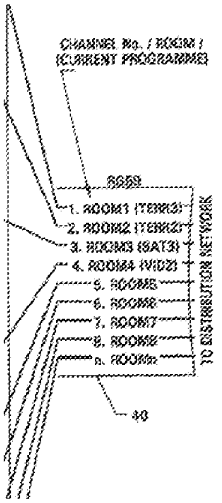
9[d] a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal;	Fisk discloses, explicitly and/or inherently, a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal. *See, e.g.*: Fisk at Fig. 4:  FIG. 4 Fisk at 24:2-8:



Asserted Claims	Fisk
	The losses over a 75 Q RG59 television coaxial cable are typically 0.13 dB/mat 100 MHz, 0.19 dB/m at 200 MHz and 0.46 dB/m at 100 GHz. Such coaxial cable can be used without modification to carry digitally encoded MPEG video. Using digital encoding, each analogue channel is transformed to a "data pipe" with over 30Mbps of capacity. This pipe is used to carry a multiplex of video channels. The number of video channels that can be carried depends on the picture quality required. For received PAL TV picture quality, typically six video channels can be carried in each pipe. Fisk at Fig. 6:  Fisk at 39:29-4-9: The server 56 will now be described in more detail, also with reference to FIG. 8. The server 56 controls the collation and distribution of stream-based media services within a hotel environment. The server 56 provides a number of classes of media content, such as terrestrial television channels, terrestrial radio channels, digital satellite television channels, and pre-digitised media assets (movies).

Exhibit B5 – Fisk Invalidity Claim Chart

Asserted Claims	Fisk
	The server 56 processes these input streams in a variety of formats (analogue, digital, compressed, encrypted, etc.) and outputs digital streams in MPEG-2 format to the switch 70 that supports Internet Group Management Protocol (IGMP). A channel controller uses IGMP to allow LCUs 66 to subscribe to any of the shared stream-based media services. The UDP/IP transport protocol is used for transmitting MPEG-2 streams to the LCU 66.\ Fisk at Tables on p. 43 & 45:

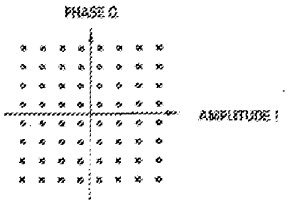
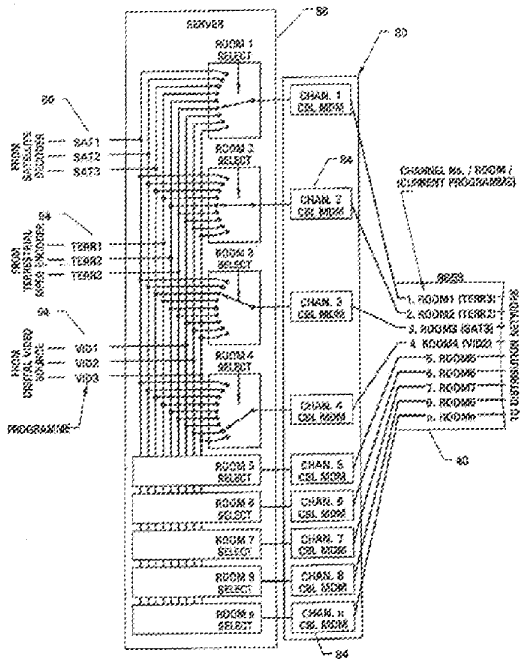
To the extent Fisk does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Fisk alone or it would have been obvious to combine Fisk with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Asserted Claims	Fisk
9[e] wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs.	Fisk discloses, explicitly and/or inherently, wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs. *See, e.g.*: Fisk at 2:13-24: One aspect of the invention provides a system for distributing television/video signals to different locations (such as different rooms in a hotel, or different dwellings in a neighbourhood), the system comprising a server capable of providing digital television/video signals for a plurality of programmes, a plurality of receivers each at a respective one of said locations, and a network connecting the server to the receivers, each receiver being operable to select a required one of the programmes and to communicate the selection to the server, the server being responsive to such a selection to transmit the digital television/video signal for the selected programme over the network addressed to the receiver that selected that programme, and each receiver being responsive to the digital television/video signal that is addressed to that receiver so that point-to-point communication is established from the server to that receiver. Fisk at 6:7-21: A further aspect of the invention provides a corresponding method of distributing television/video signals to different locations, the method comprising providing a server capable of providing digital television/video signals for a plurality of programmes, providing a plurality of receivers each at a respective one of said locations, providing a network connecting the server to the receivers, each receiver selecting a required one of the programmes and communicating the selection to the server, the server responding to such a selection and transmitting the digital television/video signal for the selected programme

Asserted Claims	Fisk
	over the network addressed to the receiver that selected that programme, and each receiver responding to the digital television/video signal that is addressed to that receiver so that point-to-point communication is established from the server to that receiver. Preferably, the transmitting includes transmitting the digital television/video signal over telephone-grade twisted-pair cable and/or transmitting the digital television/video signal over coaxial cable on a channel allocated according to the receiver to which the signal is being sent, and each receiver being tuned to its respective channel. Fisk at 22:9-23:1: In order to deal with these problems and disadvantages, the embodiment of the invention that will now be described with reference to FIG. 4 uses a switched point to-point digital distribution network 50 employing an internet protocol (IP) and in particular the user datagram protocol (UDP/IP). In the equipment room 16, the downlead 20 from the terrestrial television aerial 18 feeds a receiver and MPEG encoder 52 which provides digital MPEG video streams 54 for the received terrestrial television programmes to a server 56 (although one server 56 has been shown in the drawing, several such servers may be employed). Also, the downlead 24 from the satellite dish 22 feeds a decoder/descrambler 58 which provides digital MPEG video streams 60 for the received satellite television programmes to the server 56. Furthermore, the video replay equipment 62 has a digital output and provides digital MPEG video streams 64 for the video programmes to the server 56. The server 56 selects which of the video streams is to be transmitted to which room 12, and places the selected video streams on the digital network 50 using UDP/IP, or TCP/IP, each addressed to the selected room 12. In each room 12, the television 14 is connected to the network 50 by a local control unit (LCU) 66 that receives the video stream addressed to that room 12, decodes it, and supplies the resulting analogue video and audio signals to the television 14. Each LCU 66 is also operable to send requests over the network 38 to the server 56, for example to change the television/video channel supplied to that LCU 66. The network 50 is designed to support a bandwidth of up to 10 Mbps for communication between the server 56 and each LCU 66. The components required to deliver this

Asserted Claims	Fisk
	bandwidth will vary because of the different topology of each hotel—for example, the layout of floors, risers, and the location of the equipment room 16 in which the server(s) 56 is/are situated. Fisk at 24:15-27: Digital video over coax generally uses a 64QAM modulation scheme, where groups of 6 bits are mapped to a carrier state. Each carrier state has a unique amplitude/ carrier phase position as illustrated in FIG. 8. In order to decode 64QAM with an acceptable worst case error rate, before error correction, of 1 error in 10 bits, a signal-to-noise ratio per bit of greater than 18 dB is needed. At a smaller signal-to-noise ratio each dot in the constellation will become blurred and it will not be possible to differentiate one dot from another. A 1.5 dB difference in signal-to-noise level will make an order of magnitude difference in the error rate. Higher order QAM schemes can be used to increase the data capacity of each channel. The increased capacity is gained at the price of needing a higher signal to-noise ratio to properly decode the signal. Conversely, lower order schemes are more rugged but have a lower capacity. Fisk at Fig. 8:





Asserted Claims	Fisk
	 FIG. 8 Fisk at 28:4-19: The repartitioning of the channels on the coaxial cabling 40 is achieved by installing a cable modem termination system 80 between the server 56 and the coaxial cable network 38, and a cable modem 82 in each LCU 66. As shown in FIG. 6, the cable modem termination system 80 can be considered to comprise a cable modem 84 for each channel, and the server 56 can be considered to be able to connect each cable modem 84 selectably to any of the incoming video streams. Each cable modem 84 then transmits that video stream on a preset channel on the coaxial cable 40. As shown in FIG. 7, the cable modem 82 in each LCU 66 is preset to a particular channel, i.e. the channel for the room 12 in which the LCU 66 is situated. Each channel carried in the coaxial cable 40 can thus be dedicated to a single LCU 66. The server 56 will only transmit the service requested by the LCU 66. This is a simple architecture to install, as few cabling changes have to be made between the server 56 and room 12, and no cabling changes need to be made in the room 12. However, depending on the number of rooms served by each spur of the coaxial cable network 38, it may be necessary to modify the configuration of the coaxial cables at each riser to ensure that each spur has enough channels to support the number of rooms it is intended to serve. Fisk at 40:4-9:

Exhibit B5 – Fisk Invalidity Claim Chart

Asserted Claims	Fisk
	The server 56 processes these input streams in a variety of formats (analogue, digital, compressed, encrypted, etc.) and outputs digital streams in MPEG-2 format to the switch 70 that supports Internet Group Management Protocol (IGMP). A channel controller uses IGMP to allow LCUs 66 to subscribe to any of the shared stream-based media services. The UDP/IP transport protocol is used for transmitting MPEG-2 streams to the LCU 66. Fisk at Fig. 6:

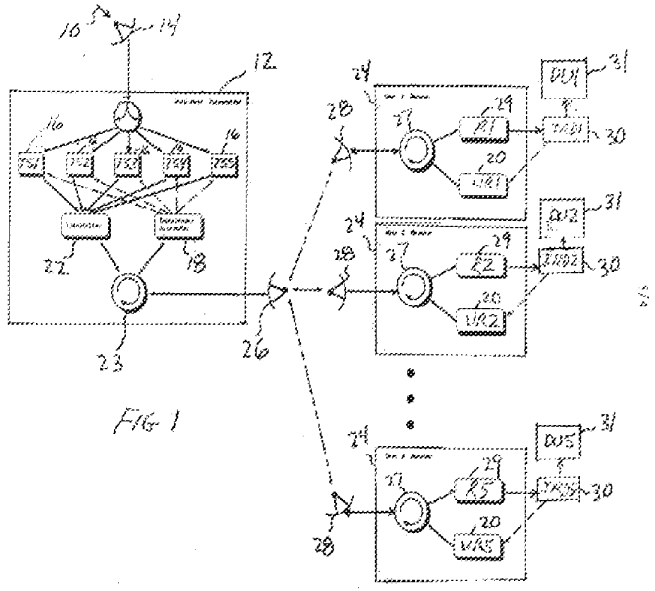
Asserted Claims	Fisk
	5/14  FIG. 6 Fisk at 41:7-24: Referring also to FIGS. 19 to 23, the server may include the following components: television and radio cards 180,182,184,188 that receive analogue RF and satellite signals and convert them to digital signals in MPEG-2 format, television and radio cards 190 that receive digital signals in MPEG-2 format; playout cards 186 that multicast an MPEG-2 or MP3 file over the hotel network; and the software for the server 56, e.g. the channel

Asserted Claims	Fisk
	manager 178, streaming components, etc. The server 56 may, for example, be presented as an 8 unit rack for mounting in a "19 inch" cabinet. Inside the cabinet there are a motherboard (e.g. Intel 700 MHz processor, 256 MB RAM, and 18 GB disk), a PCI bus 191 with 24 slots for the media cards, a 100 Mbps network card 238, power supply and fan. The server uses a DHCP client to request IP addresses for each card installed, and an SNMP client that will report any change in the status of the cards to an SNMP server in the channel controller. Each media card 180-190 installed in the server 56 is connected to the IGMP switch 70 by a Category 5 fly lead 193 from the RJ45 port 192 on the card to a port on the Switch 70. If more than one server 56 is provided, each server 56 is connected to a hub, so they can communicate with other devices on the network. As already described, the switch 70 is connected to the network 38,50 via its up-link port. The switch supports IGMP and runs at 100 Mbps. The number of ports on the switch 70 and the number of Switches will depend on each installation. To the extent Fisk does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Fisk alone or it would have been obvious to combine Fisk with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
10. The signal distribution system of claim 9 wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output.	Fisk discloses, explicitly and/or inherently, wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output. *See* claim 9, *supra*. To the extent Fisk does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Fisk alone or it would have been obvious to combine Fisk with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

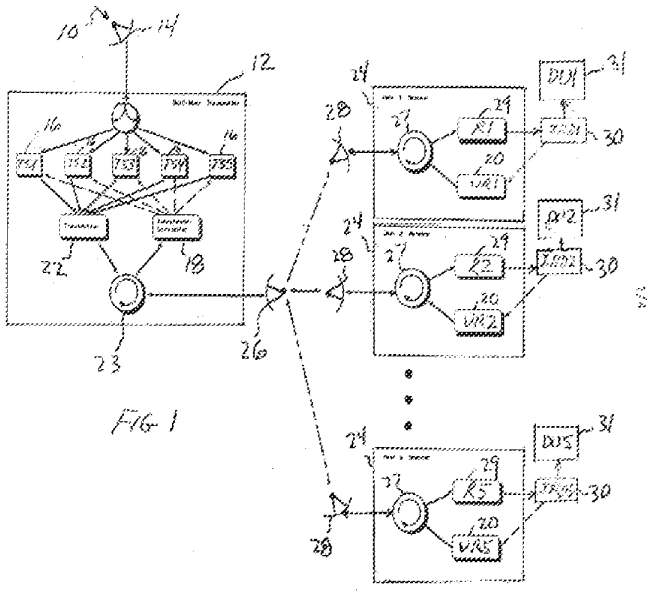
Asserted Claims	Fisk
11. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network.	Fisk discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network. *See* claim 10, *supra*. *See, e.g.*: Fisk at 40:10-19: The server 56 comprises media capture, compression, and streaming functions and includes a media manager 174 that handles media-related events. The media manager 174 collects channel and Schedule information from a configuration manager 176 and then passes messages to a specific channel manager 178. These messages detail actions that need to be taken; for example, loading an asset file, or streaming an asset on a particular card/channel. The configuration manager 176 holds a central repository of system wide information. This data is used to control many aspects of a particular installation. A subset of the configuration manager database holds information specific to the server 56. This identifies the various servers, the cards that are registered, the channels that have been assigned, the loaded media assets and the overall schedule. To the extent Fisk does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Fisk alone or it would have been obvious to combine Fisk with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
12. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the ODU and the translation table is	Fisk discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network.

Asserted Claims	Fisk
communicated to devices in the network.	*See* claim 10, *supra*. To the extent Fisk does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Fisk alone or it would have been obvious to combine Fisk with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Exhibit B6 – Gregoire Invalidity Claim Chart



INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Gregoire



International Patent Publication No. WO 00/67401 ("Gregoire") was filed as PCT No. US00/12401 on May 4, 2000 and published on November 9, 2000. Gregoire claims priority to U.S. Patent Application No. 09/305,895, which was filed on May 5, 1999. Gregoire therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(a) and/or (e). For the reasons listed below, Gregoire invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Gregoire
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Gregoire discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*: Gregoire at Abstract:

[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.

Asserted Claims	Gregoire
	A method and system for wireless Direct To Home satellite services signal distribution to a plurality of service requesting users. A multi-user transmitter is coupled to an earth satellite antenna to receive selectable satellite transponder signals. The multi-user transmitter includes a plurality of transponder selectors, each transponder selector preferably being associated with or even dedicated to a respective service-requesting user is provided with a user-controllable channel selector for accessing the selectable satellite transponder signals. The user-controllable channel selector is coupled to a respective user display unit and to a respective user receiver unit. A responder, which may be in the user receiver unit, is responsive to a service-requesting user-selected channel signal for transmitting a transponder selection signal to the multi-user transmitter. The transponder selection signal contains information indicative of a desired satellite transponder signal, to be transmitted to the service-requesting user associated with the respective (typically user-selected) channel signal. The multi-user transmitter transmits the selected satellite transponder signals to each of the plurality of service requesting users in response to the transponder selection signals, and may do so by broadcasting. The desired satellite transponder signal is then coupled to the service-requesting user receiver (which may contain the user-controllable channel selector) for display by the respective user display unit. Gregoire at 3:20-4:8: SUMMARY OF THE INVENTION In accordance with the present invention, an enhanced method and system is provided for wireless Direct To Home satellite services signal distribution to a plurality of service requesting users. Each user controls an IRD associated with a user display receiver, such as a television set. When the user switches channels on his IRD, a control processor senses the channel change. The processor uses this information to set control signals that are sent back on a wireless connection to a multiple-user transmitter unit that is connected to an earth station (satellite dish) antenna. The multi-user transmitter processes the control signals and sends them to a user's (preferably dedicated) transponder selector, which filters out a single transponder signal for transmission to the user. Several transponder signals are

Asserted Claims	Gregoire
	sent forward, one for each of the users. A typical implementation of the invention would have five to ten users and the local wireless channel would accommodate a comparable number of transponders. Each user has a receiver at his location that filters the broadcast signal from the transponder signal that he requested. A much smaller bandwidth results than that which would be required to transmit signals from all 32 transponders to each user. Gregoire at Fig. 1:  FIG 1 To the extent Gregoire does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Gregoire alone or it would have been obvious to combine Gregoire with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Asserted Claims	Gregoire
9[a] a gateway in communication with the ODU and at least one set top box (STB);	Gregoire discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Gregoire at Fig. 1:  Gregoire at 7:1-5: Transponder controller 18 is controlled by control signals from user responder units, one for each user at the user location, that determine which transponder the user wants to access. The user responder units operation is described in more 5 detail hereinafter.

Asserted Claims	Gregoire
	Gregoire at 7:6-24: Transmitter 22 bundles the transponders at the intermediate frequency band and upconverts them to a higher frequency for broadcast to the users. Circulator 23 is coupled between transmitter 22 and transponder controller 18 and transmitter/controller antenna 26. Each user has a receiver unit 24 that picks up the broadcast signal from transmitter / controller antenna 26 by user antenna 28 and through circulator 27 and receiver 29, one respectively for each user, namely Rl, R2 … RS, downconverts it and filters out the transponder signal intended for him. Each receiver 29 is coupled to an IRD 30, one for each user, namely IRD I, IRD2 15 … IRD5 which, in turn, are connected to respective display units 31, which can be television or workstation monitors, namely DUI, DU2 … DUS. Each receiver unit 24 also has user responder 20, namely URI, UR2 … URS, coupled to its respective IRD. Each user responder 20 queries its respective IRD 30 to determine the transponder requested by the user- and encodes that information for 20 transmission back to the transponder selectors in MUT 12. The control data occupies a small band adjacent to the users' transponders in the communication channel. MUT 12 has to distinguish among the control signals from the various users and direct them to the proper transponder selectors. It does this using conventional or other multiple access techniques. Gregoire at 12:1-17: 1. The transmitter Transmitter 22 bundles via multi-user combiner 43 (e.g., Narda four-way combiner Model No. 431 lC-4) all of the selector signals into a reduced bandwidth package at the intermediate frequencies. It then upconverts them to the U-NII band, bandpass filters and amplifies the signal for transmission, using frequency converter 45 which includes up-converter/ mixer 46 (e.g., Mini-Circuits Laboratories Model ZMX-7GLHR) coupled to local oscillator 48 (e.g., Luff Research Model No. SLSM2-38004300), bandpass filter 47 (e.g., K & L Microwave Model No. 51B32-5275/f400), amplifier 49 (e.g., JCA Technology Model No. JCA048-F01), circulator 23 (e.g., Narda three port circulator Model No. 4914) and transmitter/ controller antenna 26 . In an example depicted in Fig. 4,

Asserted Claims	Gregoire
	three user selected transponder signals are packaged into the U-NII band at 5150 - 5350 MHz. This is considerably smaller than the 1000 MHz necessary to transmit all the DTH transponders. Transmitter/ controller antenna 26 can be a U-NII antenna, which is a small 3" x 3" comer reflector or an 18" long, 1.25"- diameter omnidirectional antenna (e.g., Mobile Mark N SCR14-5150). Gregoire at 12:19-33: 3. The Transponder Controller "Transponder controller" (18) is abbreviated terminology for "transponder signal selector controller," for it controls a transponder selector (16) which in tum selects a transponder signal. Transponder controller 18 includes amplifier 90 (e.g., JCA Technology Model No. JCA048-F01), frequency converter 91 which includes a down-converter/ mixer 92 (e.g., Mini-Circuits Laboratories Model No. ZLMX-7GLHR) coupled to local oscillator 93 (e.g., Luff Research Model No. SLSM2-38004300), low-pass filter 94 (e.g., K&L Microwave Model No. 5IB32), demodulator 95 (e.g., BroadCom Corp. Model No. BCM93180) and processor 96 (e.g., generic 486 class personal computer processor). Transponder controller 18 receives control signals from the user in a narrow frequency band that is adjacent to the users' transponder signals (See Fig. 4). Those signals are downconverted, demodulated, processed and sent as signals 34 to LNB selectors 36 and to the tunable local oscillators (frequency synthesizer) 38 in transponder selectors 16. To the extent Gregoire does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Gregoire alone or it would have been obvious to combine Gregoire with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder	Gregoire discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a

Asserted Claims	Gregoire
signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information;	plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*: Gregoire at Abstract: A method and system for wireless Direct To Home satellite services signal distribution to a plurality of service requesting users. A multi-user transmitter is coupled to an earth satellite antenna to receive selectable satellite transponder signals. The multi-user transmitter includes a plurality of transponder selectors, each transponder selector preferably being associated with or even dedicated to a respective service-requesting user is provided with a user-controllable channel selector for accessing the selectable satellite transponder signals. The user-controllable channel selector is coupled to a respective user display unit and to a respective user receiver unit. A responder, which may be in the user receiver unit, is responsive to a service-requesting user-selected channel signal for transmitting a transponder selection signal to the multi-user transmitter. The transponder selection signal contains information indicative of a desired satellite transponder signal, to be transmitted to the service-requesting user associated with the respective (typically user-selected) channel signal. The multi-user transmitter transmits the selected satellite transponder signals to each of the plurality of service requesting users in response to the transponder selection signals, and may do so by broadcasting. The desired satellite transponder signal is then coupled to the service-requesting user receiver (which may contain the user-controllable channel selector) for display by the respective user display unit. Gregoire at 3:20-4:8: SUMMARY OF THE INVENTION

Asserted Claims	Gregoire
	In accordance with the present invention, an enhanced method and system is provided for wireless Direct To Home satellite services signal distribution to a plurality of service requesting users. Each user controls an IRD associated with a user display receiver, such as a television set. When the user switches channels on his IRD, a control processor senses the channel change. The processor uses this information to set control signals that are sent back on a wireless connection to a multiple-user transmitter unit that is connected to an earth station (satellite dish) antenna. The multi-user transmitter processes the control signals and sends them to a user's (preferably dedicated) transponder selector, which filters out a single transponder signal for transmission to the user. Several transponder signals are sent forward, one for each of the users. A typical implementation of the invention would have five to ten users and the local wireless channel would accommodate a comparable number of transponders. Each user has a receiver at his location that filters the broadcast signal from the transponder signal that he requested. A much smaller bandwidth results than that which would be required to transmit signals from all 32 transponders to each user. Gregoire at 4:29-5:9: More particularly, the multi-user transmitter is coupled to the earth satellite 30 antenna to receive selectable satellite transponder signals. The multi-user transmitter includes a plurality of transponder selectors, each transponder selector being associated with a respective service requesting user. Each service requesting user is provided with a user-controllable channel selector (IRD) for accessing the selectable satellite transponder signals. The user-controllable channel selector is coupled to a respective user display unit and to a respective user receiver unit. The user receiver unit is responsive to a service-requesting user-selected-channel signal for transmitting a transponder selection signal to the multi-user transmitter. The transponder selection signal is indicative of a desired satellite transponder signal to be transmitted to the service requesting user associated with the respective user selected channel signal. Gregoire at 6:6-18 & associated table:

Asserted Claims	Gregoire
	Fig. 1 illustrates a block diagram of an embodiment of the invention that distributes a DTH signal to multiple independent users. A five user system is illustrated. DTH signal 10 is received at satellite Earth station antenna 14 and is provided to multi-user transmitter (MUT) 12. Inside the MUT, the DTH signal is split off to five different transponder selectors 16, one for each user, namely TS 1, TS2, TS3, TS4 and TS5 for this five-user embodiment. The transponder selectors are controlled by transponder controller 18 internal to MUT 12. Each transponder selector outputs the signal from a single transponder and downconverts it in frequency so that it is centered at an intermediate frequency for further processing. Each of the users has a dedicated intermediate frequency. The table below shows an example of frequency allocations for the five user embodiment wherein the U-NII communications band is at 5150 to 5350 MHz. However, the practice of the invention is not limited to the use of this band.

User	Transponder Selector Center Frequency	MUT Frequency
User 1	400 MHz	5165 MHz
User 2	430 MHz	5195 MHz
User 3	460 MHz	5225 MHz
User 4	490 MHz	5255 MHz
User 5	520 MHz	5285 MHz
control	NA	5320 MHz

Gregoire at 11:1-28:

1. The transponder selectors

Asserted Claims	Gregoire
	There are multiple transponder selectors 16 built into MUT 12, one corresponding 5 to each user in the distribution network. "Transponder selector" is abbreviated terminology for "transponder signal selector," for it selects the signal from a single transponder from the multiple transponder signals included in the DTH signal received from the satellite. The transponder selectors each receive DTH signal 10 from the satellite antenna 14, and downconverts it to an intermediate frequency so that the desired transponder signal is re-centered about a fixed intermediate frequency dedicated to that corresponding user. The unnecessary portion of the DTH signal is filtered out and the single transponder signal is sent to MUT transmitter 22. Transponder selectors 16 each include an LNB selector 36 (a voltage-controlled Lband microwave switch), frequency converter 37 which has a down-converter mixer 40 coupled to tunable local oscillator 38, and a bandpass filter 41 (e.g., K&L Microwave Model 5TB32). Transponder selectors 16 are controlled by signals 34 from the MUT transponder controller 18 that determine which transponder signal should be output to the MUT transmitter for each user. Those signals go to a lownoise block (LNB) selector 36 (a voltage-controlled L-band microwave switch) and tunable local oscillator 38 (e.g., Luff Research frequency synthesizer PN SLSM2-5501050) controls the frequency shift in mixer 40 (e.g., Mini-Circuits Laboratories Model ZMX-lOG). In the five-user embodiment, for example, the intermediate frequencies for the five users could be situated at 400 MHz, 430 MHz, 460 MHz, 490 MHz and 520 MHz respectively. However, those skilled in the art can appreciate that the invention can be practiced by embodiments utilizing other sets of frequencies and accommodating other numbers of users. Gregoire at Claim 1: 1. A method of wireless Direct To Home satellite services signal distribution to a plurality of service-requesting users, comprising: providing a multi-user transmitter coupled to an earth satellite antenna to receive a plurality of satellite transponder signals, the multi-user transmitter including a plurality of transponder-signal selectors;

Asserted Claims	Gregoire
	providing each service-requesting user with a user-controllable channel selector for accessing the satellite transponder signals, the user-controllable channel selector being coupled to a respective user display unit and to a respective user receiver unit; transmitting to the multi-user transmitter, in response to channel selections, transponder-signal selection information indicative of desired transponder signals; transmitting transponder signals, selected according to the transponder-signal selection information, from the multi-user transmitter to respective service-requesting users associated with the channel selections; and coupling each selected satellite-transponder signal to the requesting user-controllable channel selector for display by the respective user display unit. To the extent Gregoire does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Gregoire alone or it would have been obvious to combine Gregoire with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Gregoire discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*: Gregoire at 6:6-18 & associated table: Fig. 1 illustrates a block diagram of an embodiment of the invention that distributes a DTH signal to multiple independent users. Gregoire at 7:6-24:

Transmitter 22 bundles the transponders at the intermediate frequency band and upconverts them to a higher frequency for broadcast to the users. Circulator 23 is coupled between transmitter 22 and transponder controller 18 and transmitter/controller antenna 26. Each user has a receiver unit 24 that picks up the broadcast signal from transmitter / controller antenna 26 by user antenna 28 and through circulator 27 and receiver 29, one respectively for each user, namely Rl, R2 ... RS, downconverts it and filters out the transponder signal intended for him. Each receiver 29 is coupled to an IRD 30, one for each user, namely IRD I, IRD2 15 ... IRD5 which, in turn, are connected to respective display units 31, which can be television or workstation monitors, namely DUI, DU2 ... DUS. Each receiver unit 24 also has user responder 20, namely URI, UR2 ... URS, coupled to its respective IRD. Each user responder 20 queries its respective IRD 30 to determine the transponder requested by the user- and encodes that information for 20 transmission back to the transponder selectors in MUT 12. The control data occupies a small band adjacent to the users' transponders in the communication channel. MUT 12 has to distinguish among the control

Asserted Claims	Gregoire
	signals from the various users and direct them to the proper transponder selectors. It does this using conventional or other multiple access techniques. Gregoire at 12:1-17: 1. The transmitter Transmitter 22 bundles via multi-user combiner 43 (e.g., Narda four-way combiner Model No. 431 lC-4) all of the selector signals into a reduced bandwidth package at the intermediate frequencies. It then upconverts them to the U-NII band, bandpass filters and amplifies the signal for transmission, using frequency converter 45 which includes up-converter/ mixer 46 (e.g., Mini-Circuits Laboratories Model ZMX-7GLHR) coupled to local oscillator 48 (e.g., Luff Research Model No. SLSM2-38004300), bandpass filter 47 (e.g., K & L Microwave Model No. 51B32-5275/f400), amplifier 49 (e.g., JCA Technology Model No. JCA048-F01), circulator 23 (e.g., Narda three port circulator Model No. 4914) and transmitter/ controller antenna 26 . In an example depicted in Fig. 4, three user selected transponder signals are packaged into the U-NII band at 5150 - 5350 MHz. This is considerably smaller than the 1000 MHz necessary to transmit all the DTH transponders. Transmitter/ controller antenna 26 can be a U-NII antenna, which is a small 3" x 3" comer reflector or an 18" long, 1.25"- diameter omnidirectional antenna (e.g., Mobile Mark N SCR14-5150). Gregoire at 12:19-33: 3. The Transponder Controller "Transponder controller" (18) is abbreviated terminology for "transponder signalselector controller," for it controls a transponder selector (16) which in tum selects a transponder signal. Transponder controller 18 includes amplifier 90 (e.g., JCA Technology Model No. JCA048-F01), frequency converter 91 which includes a down-converter/ mixer 92 (e.g., Mini-Circuits Laboratories Model No. ZLMX-7GLHR) coupled to local oscillator 93 (e.g., Luff Research Model No. SLSM2-38004300), low-pass filter 94 (e.g., K&L Microwave

Asserted Claims	Gregoire
	Model No. 5IB32), demodulator 95 (e.g., BroadCom Corp. Model No. BCM93180) and processor 96 (e.g., generic 486 class personal computer processor). Transponder controller 18 receives control signals from the user in a narrow frequency band that is adjacent to the users' transponder signals (See Fig. 4). Those signals are downconverted, demodulated, processed and sent as signals 34 to LNB selectors 36 and to the tunable local oscillators (frequency synthesizer) 38 in transponder selectors 16. Gregoire at Fig. 3:  FIG. 3 To the extent Gregoire does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light

Asserted Claims	Gregoire
	of Gregoire alone or it would have been obvious to combine Gregoire with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[e] wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs.	Gregoire discloses, explicitly and/or inherently, wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs. *See, e.g.*: Gregoire at 3:6-16: Therefore, there exists a need for an effective system for DTH distribution having a limited bandwidth local wireless transmission to multiple independent users in a setting where it is not possible to have a large antenna with its corresponding stringing of cable connections or where it is undesirable to erect multiple large DTH distribution antennas. Further, there is a need for an approach where the DTH signal does not need to be reformatted and exposed to noise degradation such that a high quality digital signal can be provided to the user. Also, by not decoding the signal until it reaches the TV or workstation, a variety of modulation formats (such as QPSK, FM, QAM) can be handled. Even mixed modulation formats could be utilized. Gregoire at 6:6-18 & associated table: Fig. 1 illustrates a block diagram of an embodiment of the invention that distributes a DTH signal to multiple independent users. A five user system is illustrated. DTH signal 10 is received at satellite Earth station antenna 14 and is provided to multi-user transmitter (MUT) 12. Asserted Claims	Gregoire
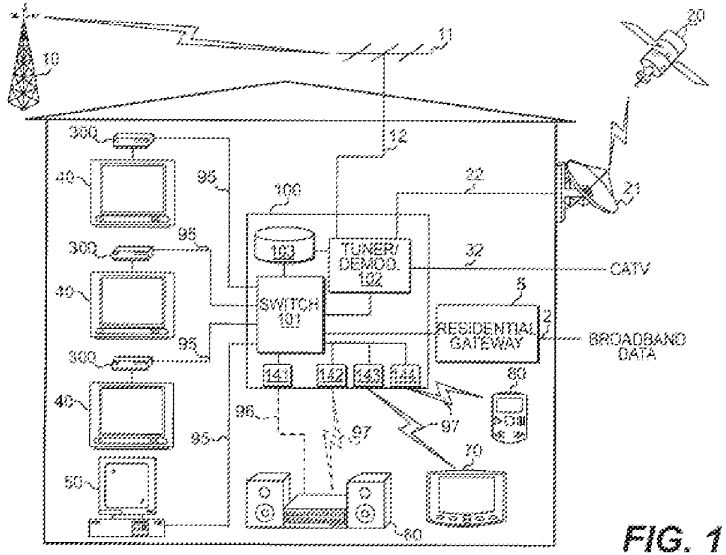
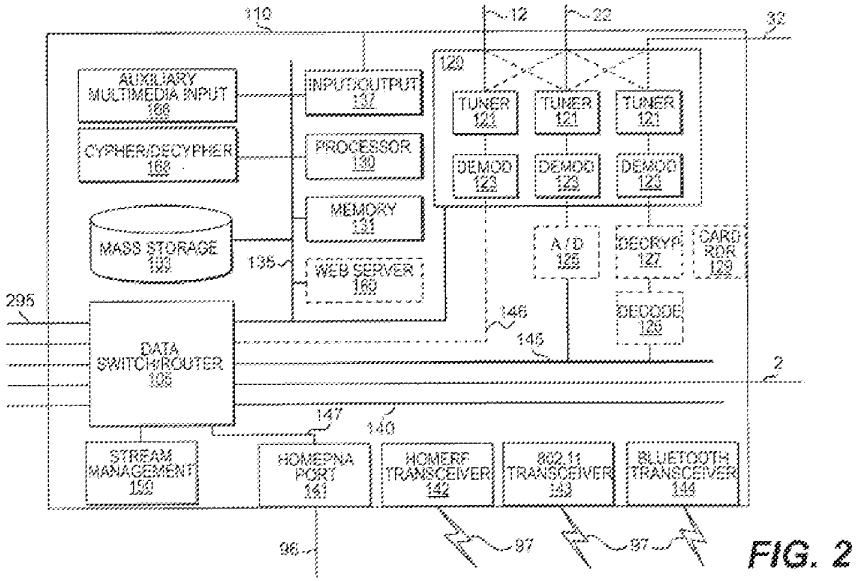
	also has user responder 20, namely URI, UR2 ... URS, coupled to its respective IRD. Each user responder 20 queries its respective IRD 30 to determine the transponder requested by the user- and encodes that information for 20 transmission back to the transponder selectors in MUT 12. The control data occupies a small band adjacent to the users' transponders in the communication channel. MUT 12 has to distinguish among the control signals from the various users and direct them to the proper transponder selectors. It does this using conventional or other multiple access techniques. To the extent Gregoire does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Gregoire alone or it would have been obvious to combine Gregoire with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.



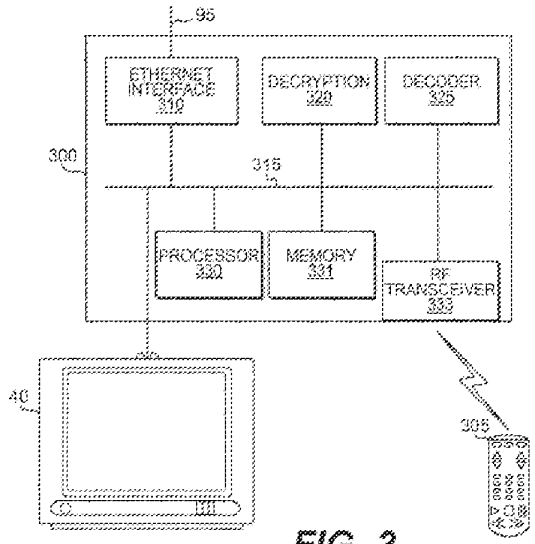
INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Hicks

U.S. Patent No. 8,601,519 B1 ("Hicks") was filed on December 28, 2000 and issued on December 3, 2013. Hicks therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(e). For the reasons listed below, Hicks invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Hicks
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Hicks discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*: Hicks at 3:35-53:



[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.



Asserted Claims	Hicks
	In the preferred embodiment of the present invention, the digital residential entertainment system is based on a client/ server architecture. A core element of the system is a broad band multimedia gateway (BMG) that can operate both as a multimedia gateway and content server within a client/server architecture. It contains an Ethernet switch that, in a typical embodiment, is capable of data communications of at least 100Mbps per switch port. The BMG can receive video, audio and other forms of multimedia content from a variety of broadcasts (e.g., direct digital broadcast satellite TV, digital cable TV, terrestrial broadcast analog and/or digital TV), Intranet, and Internet Sources. As used to describe embodiments of the present invention, the term "multimedia" encompasses video, audio, audio-video, text, graphics, facsimile, data, animation, and combinations thereof. The BMG can deliver multimedia content to a wide range of information appliances, such as digital televisions, computers, sound systems, electronic book displays, and graphical data tablets. Hicks at 6:1-16: Tuner/demodulator 102 can be coupled to one or more of a plurality of multimedia transmission systems, where each multimedia transmission system transmits a plurality of transmission signals (e.g., audio, video, television, data, etc.). Examples of multimedia transmission systems include CATV, direct broadcast satellite TV, direct broadcast satellite radio, terrestrial broadcast TV, terrestrial broadcast radio, and so forth. Tuner/demodulator 102 can be coupled to a CATV system (e.g., a headend of a CATV system) via communications link32 (e.g., a coaxial cable). A plurality of transmission signals from a direct broadcast satellite TV system including satellite 20 and satellite dish 21 can be received by tuner/ demodulator 102 via communications link 22. Also, tuner/ demodulator 102 can be coupled to a terrestrial broadcast TV system via transmitter 10, antenna 11, and communications link 12. Hicks at FIG. 1:

Asserted Claims	Hicks
	 FIG. 1 To the extent Hicks does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Hicks alone or it would have been obvious to combine Hicks with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[a] a gateway in communication with the ODU and at least one set top box (STB);	Hicks discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Hicks at 3:35-67:

Asserted Claims	Hicks
	In the preferred embodiment of the present invention, the digital residential entertainment system is based on a client/ server architecture. A core element of the system is a broad band multimedia gateway (BMG) that can operate both as a multimedia gateway and content server within a client/server architecture. It contains an Ethernet switch that, in a typical embodiment, is capable of data communications of at least 100Mbps per switch port. The BMG can receive video, audio and other forms of multimedia content from a variety of broadcasts (e.g., direct digital broadcast satellite TV, digital cable TV, terrestrial broadcast analog and/or digital TV), Intranet, and Internet Sources. As used to describe embodiments of the present invention, the term "multimedia" encompasses video, audio, audio-video, text, graphics, facsimile, data, animation, and combinations thereof. The BMG can deliver multimedia content to a wide range of information appliances, such as digital televisions, computers, sound systems, electronic book displays, and graphical data tablets. A digital residential entertainment system can include a BMG that has multiple tuner/demodulators which receive broadcast multimedia content and send the received tuner/demodulators have a shared communication link to a switch port of the Ethernet switch. Upon receiving multimedia content, the BMG can transmit the multimedia content through the Ethernet switch over the twisted pair data network to an information appliance (e.g., a thin-client digital set-top box, an audio system, a wireless MP3 player, or a wireless electronic device), store the multimedia content for future access, or transmit and store coincidentally (e.g., simultaneously). The BMG includes a mass storage device (e.g., a computer hard drive) that can store multimedia content from broadcast sources, an Intranet or the Internet. Hicks at 4:21-37: In an embodiment, the BMG can include a Web-server to support a structured, Web browser-based user interface on each information appliance coupled to the BMG, such as digital STBs, audio systems, wireless MP3 players and wireless electronic books. For example, an infrared remote control and/or an optional wireless keyboard can

Asserted Claims	Hicks
	communicate with a digital STB to interact with the Web browser-based graphical user interface that is presented on an information appliance such as a TV screen. The Web browser-based graphical user interface may be used to access broadcast and on-demand video and audio content and multimedia applications and services. Because the enhanced functionality resides in the central BMG as opposed to peripheral thick-client digital STBs, a broad range of functionality, including record/store/playback of broadcast programs, video/audio on demand, interactive TV. Web surfing, e-mail and electronic shopping, is accessible from every thin-client digital STB in the home. Hicks at 11:3-19: TC DSTB 300 can include an Ethernet interface 310 when coupled to a BMG including an Ethernet switch. When TC DSTB300 is coupled to a BMG having a different type of data switch supporting a different communications protocol (e.g., an ATM router), the TCDSTB300 can include a data switch interface compatible with that different type of data switch. TC DSTB 300 can receive a digital information signal from the data switch and process the digital information signal for output as an audio and/or video signal. For example, TC DSTB 300 can include decryption logic 320 coupled to the Ethernet interface 310 via a bus 315, and the decryption logic 320 can decrypt digital information signals that are sent by the data switch in an encrypted and/or protected format. Decoder logic 325 can also be included in TC DSTB300 to convert a digital information signal from a first digital format (e.g., a transmission format, a compressed format) to a second digital format (e.g., a display format). 	 FIG. 2 Hicks at Fig. 3:

Asserted Claims	Hicks
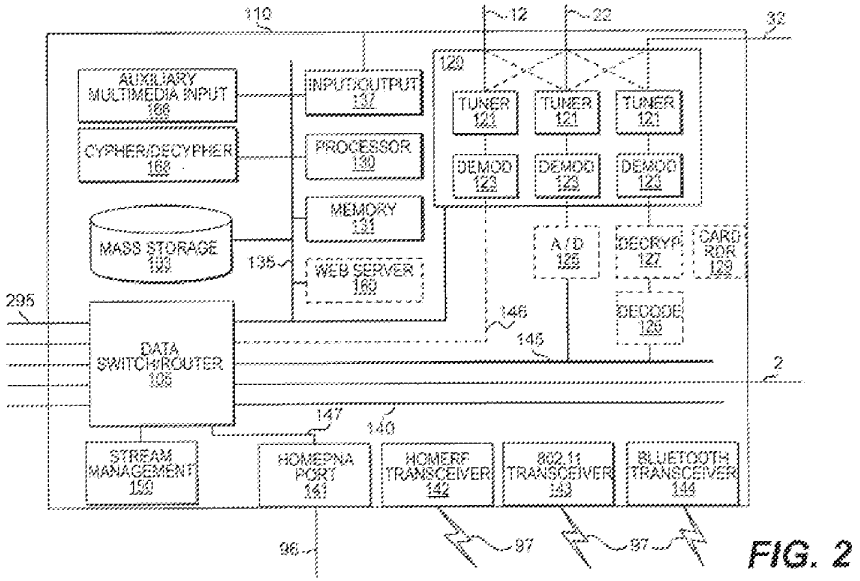
	 FIG. 3 To the extent Hicks does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Hicks alone or it would have been obvious to combine Hicks with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one	Hicks discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*:

Asserted Claims	Hicks
broadband LNB signal based on the transponder select information;	Hicks at 4:37-5:3: For example, to view broadcast video content, a consumer can use an infrared remote control to select the content that he or she wants to view by utilizing a broadcast program guide, a search function, entering a channel number, and so on. After the consumer makes a selection, the thin-client digital STB communicates with the BMG requesting that the digital multimedia content be delivered to the digital STB. When the consumer selects playing of a broadcast satellite television channel, for example, the BMG can tune a demodulator/tuner to the selected broadcast channel and begin streaming the selected MPEG video stream through the Ethernet switch and over the twisted pair wiring to the digital STB where the video steam is decoded and displayed on the TV. Service providers will be able to download multimedia content, such as movies, to the mass storage device of the BMG. The downloading can be accomplished using a broadband data service to the home, such as Asymmetric Digital Subscriber Line (ADSL), or via a satellite direct multicast/broadcast service. In a movies on-demand service, when a consumer wants to watch a movie, they would use their infrared remote control to access a Web page on the BMG Web server to determine what movies are currently stored on the BMG. After the consumer selects a movie for viewing, the BMG would begin streaming the selected movie out to the thin-client digital STB/TV for viewing. While viewing a movie-on-demand, a consumer would have playback control. Such as play, pause, stop, rewind and fast forward. The consumer could also opt to purchase a personal copy of the movie. The copy could be stored on the BMG, or output to separate mass storage medium (e.g., written to a Digital Versatile Disc). Audio content, such as an albums-on-demand service, could be implemented in a similar manner to allow playback and purchasing of audio content. Hicks at 6:17-36: The plurality of transmission signals from the multimedia transmission systems can be transmitted over a plurality of information channels, such as, for example, frequency divided information channels, time divided information channels, code divided information channels, wave divided information channels, or dense wave divided information channels. A tuner of tuner/demodulator 102 can select an information channel of the plurality of

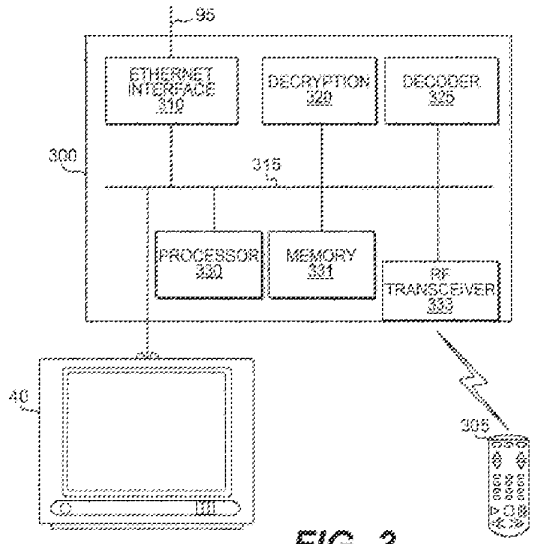
Asserted Claims	Hicks
	information channels and pass a transmission signal to a demodulator of tuner/demodulator 102. The demodulator of tuner/demodulator 102 can extract an information signal from the transmission signal. For example, a tuner can pass a transmission signal at a particular frequency to a demodulator, and the demodulator can extract the information signal from the transmission signal. In such an example, the transmission signal includes a carrier signal and an information signal. The information signal can be a discrete (i.e., singular) information signal or a multiplexed, composite information signal. For example, a multiplexed, composite information signal may contain a plurality of information signals where discrete information signals are time-division multiplexed, frequency-division multiplexed, and/or code-division multiplexed. Accordingly, tuner/demodulator 102 can include a plurality of tuners and/or demodulators to isolate an information signal that is multiply multiplexed (e.g., frequency-multiplexed and time-multiplexed). The information signal can be an analog information signal or a digital information signal. When the information signal is an analog information signal, an analog-to-digital converter can convert the analog information signal to a digital information signal (e.g., a Motion Picture Experts Group 2 (MPEG-2) signal). In an embodiment, a BMG can support multiple MPEG2 encoding sessions (e.g., two or more MPEG2 encoding sessions) and handle overlay processing. An example of overlay processing is presenting MPEG2 or other digital information in a multiple layer format. In another embodiment, a service application running on a BMG system can support transparent layers such as, for example, overlaying a Web page on top of a TV program image used for interactive TV services. Hicks at 8:23-37: Signal processing circuit 120 can include a plurality of tuners 121 and a plurality of demodulators 123, where each demodulator 123 is coupled to a tuner 121. Each tuner can be coupled to one or more communications links, e.g., communications links 12, 22, and 32. When a communication link is coupled to a plurality of tuners 121, a plurality of information signals (e.g., television programs, movies, audio, songs, albums, etc.) broadcast over a communications link can be sent to data switch/router 105 and/or mass storage device 103 to allow real-time viewing and/or playback control (e.g., viewing,

Asserted Claims	Hicks
	playing, recording, pausing, etc.) of multiple information signals. For example, a viewer at a first television may view a first CATV program, and another viewer at a second television may view a second CATV program. Further, a viewer can view a first CATV program while a second CATV program is recorded to the mass storage device. Hicks 12:38-51: The digital data switch receives an instruction to send a second information signal from the second information appliance via the second broadband communications link (box 440), and sends the instruction to send a second information signal to a processor (box 445). The processor sends a select second transmission instruction (e.g., to the multichannel tuner) (box 450). The second transmission signal of the plurality of transmission signals is selected (e.g., by the multichannel tuner) (box 455), and demodulated to isolate a second information signal (box 460). The second information signal is sent to the digital data switch (box 465), and the digital data switch sends the second information signal to the second information appliance via the second broadband communications link (box 470). To the extent Hicks does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Hicks alone or it would have been obvious to combine Hicks with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Hicks discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*: Hicks at 6:17-42:

Asserted Claims	Hicks
	The plurality of transmission signals from the multimedia transmission systems can be transmitted over a plurality of information channels, such as, for example, frequency divided information channels, time divided information channels, code divided information channels, wave divided information channels, or dense wave divided information channels. A tuner of tuner/demodulator 102 can select an information channel of the plurality of information channels and pass a transmission signal to a demodulator of tuner/demodulator 102. The demodulator of tuner/demodulator 102 can extract an information signal from the transmission signal. For example, a tuner can pass a transmission signal at a particular frequency to a demodulator, and the demodulator can extract the information signal from the transmission signal. In such an example, the transmission signal includes a carrier signal and an information signal. The information signal can be a discrete (i.e., singular) information signal or a multiplexed, composite information signal. For example, a multiplexed, composite information signal may contain a plurality of information signals where discrete information signals are time-division multiplexed, frequency-division multiplexed, and/or code-division multiplexed. Accordingly, tuner/demodulator 102 can include a plurality of tuners and/or demodulators to isolate an information signal that is multiply multiplexed (e.g., frequency-multiplexed and time-multiplexed). To the extent Hicks does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Hicks alone or it would have been obvious to combine Hicks with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[d] a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal;	Hicks discloses, explicitly and/or inherently, a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal. *See, e.g.*: Hicks at 6:17-36:



Page 1989 of 4862



Asserted Claims	Hicks
	The plurality of transmission signals from the multimedia transmission systems can be transmitted over a plurality of information channels, such as, for example, frequency divided information channels, time divided information channels, code divided information channels, wave divided information channels, or dense wave divided information channels. A tuner of tuner/demodulator 102 can select an information channel of the plurality of information channels and pass a transmission signal to a demodulator of tuner/demodulator 102. The demodulator of tuner/demodulator 102 can extract an information signal from the transmission signal. For example, a tuner can pass a transmission signal at a particular frequency to a demodulator, and the demodulator can extract the information signal from the transmission signal. In such an example, the transmission signal includes a carrier signal and an information signal. The information signal can be a discrete (i.e., singular) information signal or a multiplexed, composite information signal. For example, a multiplexed, composite information signal may contain a plurality of information signals where discrete information signals are time-division multiplexed, frequency-division multiplexed, and/or code-division multiplexed. Accordingly, tuner/demodulator 102 can include a plurality of tuners and/or demodulators to isolate an information signal that is multiply multiplexed (e.g., frequency-multiplexed and time-multiplexed). programs over a digital local area network (LAN) to STBs.	Hicks at 3:35-67: In the preferred embodiment of the present invention, the digital residential entertainment system is based on a client/server architecture. A core element of the system is a broad band multimedia gateway (BMG) that can operate both as a multimedia gateway and content server within a client/server architecture. It contains an Ethernet switch that, in a typical embodiment, is capable of data communications of at least 100Mbps per switch port. The BMG can receive video, audio and other forms of multimedia content from a variety of broadcasts (e.g., direct digital broadcast satellite TV, digital cable TV, terrestrial broadcast analog and/or digital TV), Intranet, and Internet Sources. As used to describe embodiments of the present invention, the term "multimedia" encompasses video, audio, audio-video, text, graphics, facsimile, data, animation, and combinations thereof. The BMG can deliver multimedia content to a wide range of information appliances, such as digital televisions, computers, sound systems, electronic book displays, and graphical data tablets. A digital residential entertainment system can include a BMG that has multiple tuner/demodulators which receive broadcast multimedia content and send the received tuner/demodulators have a shared communication link to a switch port of the Ethernet switch. Upon receiving multimedia content, the BMG can transmit the multimedia content through the Ethernet switch over the twisted pair data network to an information appliance (e.g., a thin-client digital set-top box, an audio system, a wireless MP3 player, or a wireless electronic device), store the multimedia content for future access, or transmit and store coincidentally (e.g., simultaneously). The BMG includes a mass storage device (e.g., a computer hard drive) that can store multimedia content from broadcast sources, an Intranet or the Internet. Hicks at 4:37-5:3: For example, to view broadcast video content, a consumer can use an infrared remote control to select the content that he or she wants to view by utilizing a broadcast program guide, a search function, entering a channel number, and so on. After the consumer makes

Asserted Claims	Hicks
	a selection, the thin-client digital STB communicates with the BMG requesting that the digital multimedia content be delivered to the digital STB. When the consumer selects playing of a broadcast satellite television channel, for example, the BMG can tune a demodulator/tuner to the selected broadcast channel and begin streaming the selected MPEG video stream through the Ethernet switch and over the twisted pair wiring to the digital STB where the video steam is decoded and displayed on the TV. Service providers will be able to download multimedia content, such as movies, to the mass storage device of the BMG. The downloading can be accomplished using a broadband data service to the home, such as Asymmetric Digital Subscriber Line (ADSL), or via a satellite direct multicast/broadcast service. In a movies on-demand service, when a consumer wants to watch a movie, they would use their infrared remote control to access a Web page on the BMG Web server to determine what movies are currently stored on the BMG. After the consumer selects a movie for viewing, the BMG would begin streaming the selected movie out to the thin-client digital STB/TV for viewing. While viewing a movie-on-demand, a consumer would have playback control. Such as play, pause, stop, rewind and fast forward. The consumer could also opt to purchase a personal copy of the movie. The copy could be stored on the BMG, or output to separate mass storage medium (e.g., written to a Digital Versatile Disc). Audio content, such as an albums-on-demand service, could be implemented in a similar manner to allow playback and purchasing of audio content. Hicks at 6:43-56: The information signal can be an analog information signal or a digital information signal. When the information signal is an analog information signal, an analog-to-digital converter can convert the analog information signal to a digital information signal (e.g., a Motion Picture Experts Group 2 (MPEG-2) signal). In an embodiment, a BMG can support multiple MPEG2 encoding sessions (e.g., two or more MPEG2 encoding sessions) and handle overlay processing. An example of overlay processing is presenting MPEG2 or other digital information in a multiple layer format. In another embodiment, a service application running on a BMG system can support transparent layers such as, for example, overlaying a Web page on top of a TV program image used for interactive TV services.

Asserted Claims	Hicks
	Hicks at 7:56-67: In accordance with an embodiment of the present invention, multiple information appliances can receive a digital information signal from data switch 101. For example, a television program broadcast by a CATV system can be received by BMG 100, and BMG can send that television program to a plurality of televisions 40 and/or computer 50 such that a user at an information appliance views the television program in real-time. BMG 100 can also store that television program on mass storage device 103 so that a user can view the television program at a later time on one or more of the information appliances (e.g., televisions 40 and/or computer 50). Hicks at 11:48-12:3: FIG. 6 illustrates another embodiment of the present invention. A BMG 600 can include a plurality of buses to interconnect BMG components. For example, the plurality of buses can include a media bus 610, a network bus 615, and a system data bus 620. Media bus 610 can receive information signals (e.g., broadcast signals, multimedia signals, and so on) from signal processing circuit 120. In an embodiment, signal processing circuit 120 and media bus 610 are coupled via system cipher/dechiper [sic] logic 628. System data bus 620 can be coupled to the media bus 610 to receive information signals (e.g., for storage on mass storage device 103, for sending to information appliances, and so on). In an embodiment, media bus 610 and system data bus 620 can be coupled to a video overlay processor 605 to support at least in part picture-in picture operations, picture-in-graphic operations, and other video overlay operations. System data bus 620 can be coupled to data switch/router 105 via network bus 615 to receive information signals (e.g., real-time information signals), overlayed information signals and stored information signals (e.g., stored on mass storage device 103). Data switch/router 105 can be coupled to a plurality of high bandwidth communications links 95 for transmission of information signals to information appliances. Hicks at Fig. 2:

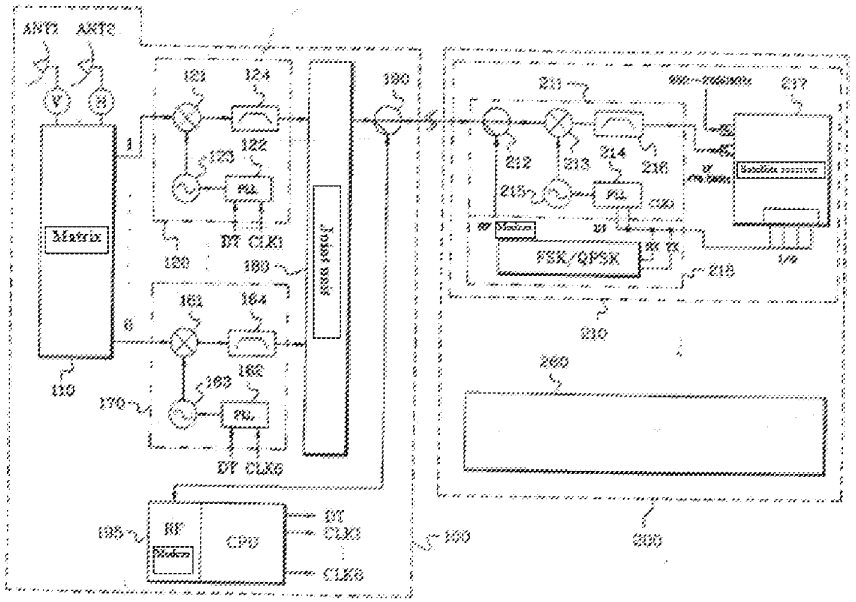
Exhibit B8 – Kang Invalidity Claim Chart

INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Kang

Korean Patent No. KR0142730 ("Kang") was filed on April 4, 1995 published on November 25, 1996. Kang therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(a) and/or (b). For the reasons listed below, Kang invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Kang
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Kang discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*: Kang at Abstract:



[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.

Asserted Claims	Kang
	A satellite broadcast joint reception circuit advantageous for transmitting to a small number of subscribers through a joint reception system line after receiving and distributing satellite broadcast through a joint antenna is posted. This is composed of a transmission circuit that selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and the unique clock of each subscriber in the satellite broadcast received through the central antenna, modulates each FM in the UHF band, and combines them for output, and a reception circuit that, after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the predetermined number of UHF-FM modulated channel frequencies that are combined and output from the transmitting circuit, has a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to a satellite receiver. After selecting and receiving horizontal and vertical polarization satellite signals using a joint antenna, a predetermined channel is selected by each subscriber's tuning data and unique clock, modulated with UHF-FM, and transmitted through a joint reception system line, and each subscriber's receiver in the public area converts the UHF-FM signal of the channel selected by each subscriber into a satellite intermediate frequency. By doing so, paid channels and stereo are made possible, and as not as many demodulators and modulators as the number of satellite channels are required, the costs can be reduced and are suitable for a small system. Kang at 1: In general, the Satellite Master Antenna Television (hereinafter abbreviated as "SMATV") is a system that receives satellite broadcasts through a central antenna used jointly and distributes them to public service areas (e.g., apartments, hotels, hospitals, etc.). Kang at 1: Fig. 1 is a block diagram showing such a conventional satellite broadcast joint reception circuit. A satellite signal received through a joint antenna (ANT) is distributed to a predetermined number of channels by the distributing unit (10).

Asserted Claims	Kang
	Kang at 1: The features of the satellite broadcast joint reception circuit according to the present invention for achieving the above purpose are its composition: in a satellite broadcast joint reception circuit for receiving satellite broadcasts through a jointly used central antenna and distributing them to the public service area, in the satellite broadcast received through the central antenna, each subscriber selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and a unique clock of each subscriber, frequency-modulates each channel in the microwave band, and combines and outputs them, and after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the channel frequencies of the microwave frequency-modulated composition output combined and output by the transmitting means, a receiving means is provided with a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to the satellite receiver. Kang at 2: In Fig. 2, it is composed of a transmission circuit (100), an outdoor unit that transmits satellite broadcasting received through two central satellite antennas (ANT1, ANT2) used jointly to each subscriber in the public service area, and a reception circuit (200), an indoor unit composed of each subscriber in the public service area. Kang at 2: Here, the transmission circuit (100) serving as an outdoor unit and the reception circuit (200) serving as an indoor unit are connected by a coaxial cable. Kang at 2: Here, the matrix (110) includes first and second low noise clocks (Low Noise Block; hereinafter referred to as LNB) (111, 112) connected to the respective antennas (ANT1,

Asserted Claims	Kang
	ANT2), a power supply unit (113) for supplying 14 V or more of DC, that is, 14 V or 18 V, to the LNBs (111, 112), the first and second dividers (114, 115) that distribute the vertical polarization (V) or horizontal polarization (B) satellite signals output through the first and second LNBs (111, 112) according to the voltage supplied from the power supply unit (113) by the number of subscribers in the public service area, and a predetermined number of switching elements (116, 117) corresponding to the number of subscribers in the public service area that switches the vertical polarization (V) and horizontal polarization (H) satellite signals output from the first and second dividers (114, 115) by control signals (a, b) and output them the tuning unite (120 [] 170). Kang at 2: That is, when 14 V is supplied to the first LNB (111) from the power supply unit (113), and 18 V is supplied to the second LNB (112), the first LNB (111) outputs only the vertically polarized satellite signal (V), and the second LNB (112) outputs only the horizontally polarized satellite signal (H). Kang at 3: In this invention configured as described above, when a satellite signal is received through the two central antennas (ANT1, ANT2) used jointly, the power supply unit (113) of the matrix (110) of the transmission circuit (100) supplies 14 V to the first LNB (111) and 18 V to the second LNB (112). Kang at 3: Accordingly, the first LNB (111) receives only the vertical polarized satellite signal (V), and the second LNB (113) receives only the horizontally polarized satellite signal (H) and outputs it to the divider (114, 115) connected to each output terminal. Kang at 3:

Asserted Claims	Kang
	At this time, to receive a horizontally polarized satellite signal through the first LNB (111) and a vertical polarized satellite signal through the second LNB (112), 18 V can be supplied from the power supply unit (113) to the first LNB (111) and 14 V to the second LNB (112). Kang:  To the extent Kang does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Kang alone or it would have been obvious to combine Kang with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Asserted Claims	Kang
9[a] a gateway in communication with the ODU and at least one set top box (STB);	Kang discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Kang at 3: At this time, the first subscriber circuit (210) is composed of a tuning unit (211) that converts the frequency corresponding to the channel selection data value (DT) output from the first subscriber circuit (210) among the frequencies output from the transmission circuit (100) into an intermediate frequency and outputs the converted frequency to the satellite receiver (217) and an RF modem (218) for outputting the channel selection data (DT) to the control unit (195) of the transmission circuit (100) through the tuning unit (211) according to the channel selection in the satellite receiver (217). Kang at 3: Here, the tuning unit (211) is composed of a divider (212) for receiving a satellite signal transmitted through the divider (190) of the transmission circuit (100) or for outputting the channel selection data output from the RF modem (218) to the transmission circuit (100), a mixer (213) that mixes and outputs the generator frequency corresponding to the selected channel and the satellite broadcast frequency output through the divider (212), a PLL (214) that always maintains a constant signal frequency of an output according to the channel selection data (DT) output from the above RF modem (218) and a unique clock (CLK1) of each subscriber, a generator (215) that generates according to the output of the PLL (214) and outputs it to the mixer (213), and a SAW filter (216) that passes only a predetermined frequency among the frequencies output from the mixer (213). To the extent Kang does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light

Asserted Claims	Kang
	of Kang alone or it would have been obvious to combine Kang with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information;	Kang discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*: Kang at Abstract: A satellite broadcast joint reception circuit advantageous for transmitting to a small number of subscribers through a joint reception system line after receiving and distributing satellite broadcast through a joint antenna is posted. This is composed of a transmission circuit that selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and the unique clock of each subscriber in the satellite broadcast received through the central antenna, modulates each FM in the UHF band, and combines them for output, and a reception circuit that, after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the predetermined number of UHF-FM modulated channel frequencies that are combined and output from the transmitting circuit, has a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to a satellite receiver. After selecting and receiving horizontal and vertical polarization satellite signals using a joint antenna, a predetermined channel is selected by each subscriber's tuning data and unique clock, modulated with UHF-FM, and transmitted through a joint reception system line, and each subscriber's receiver in the public area converts the UHF-FM signal of the channel selected by each subscriber into a satellite intermediate frequency. By doing so, paid channels and stereo are

Asserted Claims	Kang
	made possible, and as not as many demodulators and modulators as the number of satellite channels are required, the costs can be reduced and are suitable for a small system. Kang at 1: The features of the satellite broadcast joint reception circuit according to the present invention for achieving the above purpose are its composition: in a satellite broadcast joint reception circuit for receiving satellite broadcasts through a jointly used central antenna and distributing them to the public service area, in the satellite broadcast received through the central antenna, each subscriber selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and a unique clock of each subscriber, frequency-modulates each channel in the microwave band, and combines and outputs them, and after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the channel frequencies of the microwave frequency-modulated composition output combined and output by the transmitting means, a receiving means is provided with a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to the satellite receiver. Kang at 2: In Fig. 2, it is composed of a transmission circuit (100), an outdoor unit that transmits satellite broadcasting received through two central satellite antennas (ANT1, ANT2) used jointly to each subscriber in the public service area, and a reception circuit (200), an indoor unit composed of each subscriber in the public service area. Kang at 2: Here, the transmission circuit (100) serving as an outdoor unit and the reception circuit (200) serving as an indoor unit are connected by a coaxial cable. Kang at 2:

Asserted Claims	Kang
	At this time, the transmission circuit (100) receives vertical polarization (V) and horizontal polarization (H) satellite broadcasts through two common antenna (ANT1, ANT2), respectively, and then a matrix(110) that distributes satellites signals as many as the number of subscribers is connected to a tuning unit (120 [] 170) that has a unique clock of each subscriber and selects a predetermined channel according to the channel selection data (DT) output from each subscriber. Kang at 2: Here, the matrix (110) includes first and second low noise clocks (Low Noise Block; hereinafter referred to as LNB) (111, 112) connected to the respective antennas (ANT1, ANT2), a power supply unit (113) for supplying 14 V or more of DC, that is, 14 V or 18 V, to the LNBs (111, 112), the first and second dividers (114, 115) that distribute the vertical polarization (V) or horizontal polarization (B) satellite signals output through the first and second LNBs (111, 112) according to the voltage supplied from the power supply unit (113) by the number of subscribers in the public service area, and a predetermined number of switching elements (116, 117) corresponding to the number of subscribers in the public service area that switches the vertical polarization (V) and horizontal polarization (H) satellite signals output from the first and second dividers (114, 115) by control signals (a, b) and output them the tuning unite (120 [] 170). Kang at 2: And, the first tuning unit (120) of the transmission circuit (100) is composed of a mixer (121) that mixes and outputs the frequencies of satellite broadcasting output from the matrix (110) of generator frequencies corresponding to the selected channel, a Phase Locked Loop (hereinafter referred to as PLL) (122) that always keeps the signal frequency of the output constant according to the channel selection data (DT) and a unique clock (CLK1) of each subscriber, a generator (123) that generates according to the output of the PLL (122) and outputs it the mixer (121), and a filter (124) that passes only a predetermined frequency among frequencies output from the mixer (121).

Asserted Claims	Kang
	Kang at 4: At this time, taking each subscriber as an example, when the first subscriber of the first subscriber circuit (210) of the reception circuit (200) selects a channel through the satellite receiver (217), the channel data (DT) and the unique clock (CLK1) of the first subscriber are transmitted to the RF modem of the control unit (195) of the reception circuit (100) through the RF modem (210). Kang at 4: Also, the RF modem of the control unit (195) outputs the channel data (DT) and the unique clock (CLK1) of the first subscriber to the PLL (122) of the tuning unit (120) of the first subscriber, and the PLL (122) maintains a constant signal frequency of the output according to the channel selection data (DT) and the unique clock (CLK1) and outputs the output to the generator (123). Kang at 4: Here, the generator (123) controlled by I²C generates according to the output of the PLL (122) and outputs a generator frequency to the mixer (121), then the mixer (121) mixes the generator frequency with the vertically or horizontally polarized satellite signal output from the matrix (110) and outputs it to the joint unit (180) through the SAW filter (124). Kang at 4: In other words, the signal output from the tuning unit (120) is a channel frequency tuned by the first subscriber and is FM-modulated and output in the UHF band. Kang at 5:

Asserted Claims	Kang
	Meanwhile, when the satellite receiver (217) of the first subscriber circuit (210) selects a channel, the channel selection data is output to the RF modem (218) through the signal input/output terminal (I/O), and the RF modem (218) outputs the channel selection data (DT) and the clock (CLK1) to the control unit (195) of the transmission circuit (100) and the PLL (214) of the first subscriber circuit (210) of the reception circuit (200). Kang at 5: The PLL (214) maintains a constant output signal frequency according to the channel selection data (DT) and the clock (CLK1) of the first subscriber and outputs it to the generator (215). Kang at 5: The generator (215) controlled by I²C generates according to the output of the PLL (214) and outputs a generator frequency to the mixer (213), and the mixer (213) mixes the generator frequency with the satellite signal in the divider (212) and outputs the mix. Kang at 5: In other words, when a predetermined number of channel frequencies are combined and output in the transmission circuit (100), only the frequency of the channel selected by the first subscriber based on the channel data (DT) and the clock (CLK1) selected by the first subscriber is output through the mixer (213). To the extent Kang does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Kang alone or it would have been obvious to combine Kang with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Asserted Claims	Kang
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Kang discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*: Kang at Abstract: A satellite broadcast joint reception circuit advantageous for transmitting to a small number of subscribers through a joint reception system line after receiving and distributing satellite broadcast through a joint antenna is posted. This is composed of a transmission circuit that selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and the unique clock of each subscriber in the satellite broadcast received through the central antenna, modulates each FM in the UHF band, and combines them for output, and a reception circuit that, after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the predetermined number of UHF-FM modulated channel frequencies that are combined and output from the transmitting circuit, has a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to a satellite receiver. After selecting and receiving horizontal and vertical polarization satellite signals using a joint antenna, a predetermined channel is selected by each subscriber's tuning data and unique clock, modulated with UHF-FM, and transmitted through a joint reception system line, and each subscriber's receiver in the public area converts the UHF-FM signal of the channel selected by each subscriber into a satellite intermediate frequency. By doing so, paid channels and stereo are made possible, and as not as many demodulators and modulators as the number of satellite channels are required, the costs can be reduced and are suitable for a small system. Kang at 1:

Asserted Claims	Kang
	The features of the satellite broadcast joint reception circuit according to the present invention for achieving the above purpose are its composition: in a satellite broadcast joint reception circuit for receiving satellite broadcasts through a jointly used central antenna and distributing them to the public service area, in the satellite broadcast received through the central antenna, each subscriber selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and a unique clock of each subscriber, frequency-modulates each channel in the microwave band, and combines and outputs them, and after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the channel frequencies of the microwave frequency-modulated composition output combined and output by the transmitting means, a receiving means is provided with a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to the satellite receiver. Kang at 2: And, the first tuning unit (120) of the transmission circuit (100) is composed of a mixer (121) that mixes and outputs the frequencies of satellite broadcasting output from the matrix (110) of generator frequencies corresponding to the selected channel, a Phase Locked Loop (hereinafter referred to as PLL) (122) that always keeps the signal frequency of the output constant according to the channel selection data (DT) and a unique clock (CLK1) of each subscriber, a generator (123) that generates according to the output of the PLL (122) and outputs it the mixer (121), and a filter (124) that passes only a predetermined frequency among frequencies output from the mixer (121). Kang at 3: Also, the joint unit (180) for combining the corresponding frequency according to the channel selection output from each of the tuning units (120 [] 170) is connected to each tuning unit (120 [] 170), and a divider (190) for distributing satellite signals to each

Asserted Claims	Kang
	subscriber of the reception circuit (200) is connected to the output terminal of the joint unit (180). Kang at 3: At this time, the first subscriber circuit (210) is composed of a tuning unit (211) that converts the frequency corresponding to the channel selection data value (DT) output from the first subscriber circuit (210) among the frequencies output from the transmission circuit (100) into an intermediate frequency and outputs the converted frequency to the satellite receiver (217) and an RF modem (218) for outputting the channel selection data (DT) to the control unit (195) of the transmission circuit (100) through the tuning unit (211) according to the channel selection in the satellite receiver (217). Kang at 3: Here, the tuning unit (211) is composed of a divider (212) for receiving a satellite signal transmitted through the divider (190) of the transmission circuit (100) or for outputting the channel selection data output from the RF modem (218) to the transmission circuit (100), a mixer (213) that mixes and outputs the generator frequency corresponding to the selected channel and the satellite broadcast frequency output through the divider (212), a PLL (214) that always maintains a constant signal frequency of an output according to the channel selection data (DT) output from the above RF modem (218) and a unique clock (CLK1) of each subscriber, a generator (215) that generates according to the output of the PLL (214) and outputs it to the mixer (213), and a SAW filter (216) that passes only a predetermined frequency among the frequencies output from the mixer (213). Kang at 3: In this case, the RF modem (218) modulates the signal using Frequency Shift Keying (FSK) or Quad Phase Shift Keying (QPSK).

Asserted Claims	Kang
	Kang at 3: Here, frequency shift keying is a frequency modulation method in which the transmission data "1" and "0" correspond to two frequencies and the amplitude is constant, and compared to amplitude modulation, it is less susceptible to level fluctuations or noise. Kang at 5: Furthermore, the UHF-FM signal output from the mixer (213) is converted to a satellite intermediate frequency (e.g. 479.5 MHz) through the SAW filter (216), so that the satellite receiver (217), which is the frequency of the channel selected by the first subscriber, can recognize it, and then output to the satellite receiver (217). Kang at 5: Similarly, in the second to sixth subscriber circuits, through the same operation as in the first subscriber circuit (210), only the frequency of the channel selected by each subscriber is selected in each subscriber circuit and then converted to a satellite intermediate frequency and output to the satellite receiver of each subscriber circuit. To the extent Kang does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Kang alone or it would have been obvious to combine Kang with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[d] a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal;	Kang discloses, explicitly and/or inherently, a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal.

Asserted Claims	Kang
	See, e.g.: Kang at Abstract: A satellite broadcast joint reception circuit advantageous for transmitting to a small number of subscribers through a joint reception system line after receiving and distributing satellite broadcast through a joint antenna is posted. This is composed of a transmission circuit that selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and the unique clock of each subscriber in the satellite broadcast received through the central antenna, modulates each FM in the UHF band, and combines them for output, and a reception circuit that, after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the predetermined number of UHF-FM modulated channel frequencies that are combined and output from the transmitting circuit, has a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to a satellite receiver. After selecting and receiving horizontal and vertical polarization satellite signals using a joint antenna, a predetermined channel is selected by each subscriber's tuning data and unique clock, modulated with UHF-FM, and transmitted through a joint reception system line, and each subscriber's receiver in the public area converts the UHF-FM signal of the channel selected by each subscriber into a satellite intermediate frequency. By doing so, paid channels and stereo are made possible, and as not as many demodulators and modulators as the number of satellite channels are required, the costs can be reduced and are suitable for a small system. Kang at 1: Furthermore, the frequencies of the modulated predetermined channels are combined in the joint unit (40) and then transmitted through a joint reception system line. Kang at 1:

Asserted Claims	Kang
	The features of the satellite broadcast joint reception circuit according to the present invention for achieving the above purpose are its composition: in a satellite broadcast joint reception circuit for receiving satellite broadcasts through a jointly used central antenna and distributing them to the public service area, in the satellite broadcast received through the central antenna, each subscriber selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and a unique clock of each subscriber, frequency-modulates each channel in the microwave band, and combines and outputs them, and after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the channel frequencies of the microwave frequency-modulated composition output combined and output by the transmitting means, a receiving means is provided with a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to the satellite receiver. Kang at 3: Also, the joint unit (180) for combining the corresponding frequency according to the channel selection output from each of the tuning units (120 [] 170) is connected to each tuning unit (120 [] 170), and a divider (190) for distributing satellite signals to each subscriber of the reception circuit (200) is connected to the output terminal of the joint unit (180). Kang at 5: In other words, when a predetermined number of channel frequencies are combined and output in the transmission circuit (100), only the frequency of the channel selected by the first subscriber based on the channel data (DT) and the clock (CLK1) selected by the first subscriber is output through the mixer (213).

Asserted Claims	Kang
	To the extent Kang does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Kang alone or it would have been obvious to combine Kang with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[e] wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs.	Kang discloses, explicitly and/or inherently, wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs. *See, e.g.*: Kang at Abstract: A satellite broadcast joint reception circuit advantageous for transmitting to a small number of subscribers through a joint reception system line after receiving and distributing satellite broadcast through a joint antenna is posted. After selecting and receiving horizontal and vertical polarization satellite signals using a joint antenna, a predetermined channel is selected by each subscriber's tuning data and unique clock, modulated with UHF-FM, and transmitted through a joint reception system line, and each subscriber's receiver in the public area converts the UHF-FM signal of the channel selected by each

Asserted Claims	Kang
	subscriber into a satellite intermediate frequency. By doing so, paid channels and stereo are made possible, and as not as many demodulators and modulators as the number of satellite channels are required, the costs can be reduced and are suitable for a small system. Kang at 1: At this time, the satellite signal transmitted through the joint reception system line is amplified by the amplifier (50), then distributed by the divider (60) and input into the TVs in the public service areas (e.g., apartments, hotels, hospitals, buildings, etc.) connected to the joint reception system line. Kang at 1: Furthermore, the frequencies of the modulated predetermined channels are combined in the joint unit (40) and then transmitted through a joint reception system line. Kang at 1: The features of the satellite broadcast joint reception circuit according to the present invention for achieving the above purpose are its composition: in a satellite broadcast joint reception circuit for receiving satellite broadcasts through a jointly used central antenna and distributing them to the public service area, in the satellite broadcast received through the central antenna, each subscriber selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and a unique clock of each subscriber, frequency-modulates each channel in the microwave band, and combines and outputs them, and after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the channel frequencies of the microwave frequency-modulated composition output combined and output by the transmitting means, a receiving means is provided with a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to the satellite receiver.

Asserted Claims	Kang
	Kang at 2: Here, the matrix (110) includes first and second low noise clocks (Low Noise Block; hereinafter referred to as LNB) (111, 112) connected to the respective antennas (ANT1, ANT2), a power supply unit (113) for supplying 14 V or more of DC, that is, 14 V or 18 V, to the LNBs (111, 112), the first and second dividers (114, 115) that distribute the vertical polarization (V) or horizontal polarization (B) satellite signals output through the first and second LNBs (111, 112) according to the voltage supplied from the power supply unit (113) by the number of subscribers in the public service area, and a predetermined number of switching elements (116, 117) corresponding to the number of subscribers in the public service area that switches the vertical polarization (V) and horizontal polarization (H) satellite signals output from the first and second dividers (114, 115) by control signals (a, b) and output them the tuning unite (120 [] 170). Kang at 3: Also, the joint unit (180) for combining the corresponding frequency according to the channel selection output from each of the tuning units (120 [] 170) is connected to each tuning unit (120 [] 170), and a divider (190) for distributing satellite signals to each subscriber of the reception circuit (200) is connected to the output terminal of the joint unit (180). Kang at 3: At this time, the first subscriber circuit (210) is composed of a tuning unit (211) that converts the frequency corresponding to the channel selection data value (DT) output from the first subscriber circuit (210) among the frequencies output from the transmission circuit (100) into an intermediate frequency and outputs the converted frequency to the satellite receiver (217) and an RF modem (218) for outputting the channel selection data (DT) to

Asserted Claims	Kang
	the control unit (195) of the transmission circuit (100) through the tuning unit (211) according to the channel selection in the satellite receiver (217). Kang at 3: Here, the tuning unit (211) is composed of a divider (212) for receiving a satellite signal transmitted through the divider (190) of the transmission circuit (100) or for outputting the channel selection data output from the RF modem (218) to the transmission circuit (100), a mixer (213) that mixes and outputs the generator frequency corresponding to the selected channel and the satellite broadcast frequency output through the divider (212), a PLL (214) that always maintains a constant signal frequency of an output according to the channel selection data (DT) output from the above RF modem (218) and a unique clock (CLK1) of each subscriber, a generator (215) that generates according to the output of the PLL (214) and outputs it to the mixer (213), and a SAW filter (216) that passes only a predetermined frequency among the frequencies output from the mixer (213). Kang at 3: Accordingly, the first LNB (111) receives only the vertical polarized satellite signal (V), and the second LNB (113) receives only the horizontally polarized satellite signal (H) and outputs it to the divider (114, 115) connected to each output terminal. Kang at 4: On the other hand, as the first divider (114) that receives the vertically polarized satellite signal (V) and the second divider (115) that receives the horizontally polarized satellite signal (H) distribute the satellite signal to 6 channels since it is assumed that the number of subscribers in the public service area is 6. Kang at 4:

Asserted Claims	Kang
	The joint unit (180) outputs the satellite frequency of the tuned channel to each of the subscriber circuits (210, 260) of the reception circuit (200) through the divider (190). Kang at 4: In this case, taking the first subscriber as an example, when an error occurs in the first subscriber circuit (210) of the RF modem (218) of the tuning unit (211) of the first subscriber circuit (210), the error is transmitted, and when a channel is selected, the channel selection data (DT) is transmitted to the RF modem of the control unit (195) of the transmission circuit (100) through the divider (212) together with the first subscriber's unique clock (CLK1). Kang at 4: In other words, it is a bidirectional coaxial cable that, when the divider (212) receives a satellite signal from the transmission circuit (100) or when an error occurs in the first subscriber circuit (210), outputs the error, and outputs the channel data to the control unit (195) of the transmission circuit (100) together with a unique clock (CLK1) when a channel is selected. Kang at 4: Accordingly, the FM-modulated satellite signal in the UHF band received through the divider (212) is output to the mixer (213). Kang at 5: The generator (215) controlled by I²C generates according to the output of the PLL (214) and outputs a generator frequency to the mixer (213), and the mixer (213) mixes the generator frequency with the satellite signal in the divider (212) and outputs the mix.

Asserted Claims	Kang
	Kang at 5: In other words, when a predetermined number of channel frequencies are combined and output in the transmission circuit (100), only the frequency of the channel selected by the first subscriber based on the channel data (DT) and the clock (CLK1) selected by the first subscriber is output through the mixer (213). To the extent Kang does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Kang alone or it would have been obvious to combine Kang with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
10. The signal distribution system of claim 9 wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output.	Kang discloses, explicitly and/or inherently, wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output. *See* claim 9, *supra*. *See, e.g.*: Kang at Abstract: A satellite broadcast joint reception circuit advantageous for transmitting to a small number of subscribers through a joint reception system line after receiving and distributing satellite broadcast through a joint antenna is posted. This is composed of a transmission circuit that selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and the unique clock of each subscriber in the satellite broadcast received through the central antenna, modulates each FM in the UHF band, and combines them for output, and a reception circuit that, after

Asserted Claims	Kang
	selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the predetermined number of UHF-FM modulated channel frequencies that are combined and output from the transmitting circuit, has a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to a satellite receiver. After selecting and receiving horizontal and vertical polarization satellite signals using a joint antenna, a predetermined channel is selected by each subscriber's tuning data and unique clock, modulated with UHF-FM, and transmitted through a joint reception system line, and each subscriber's receiver in the public area converts the UHF-FM signal of the channel selected by each subscriber into a satellite intermediate frequency. By doing so, paid channels and stereo are made possible, and as not as many demodulators and modulators as the number of satellite channels are required, the costs can be reduced and are suitable for a small system. Kang at 1: The features of the satellite broadcast joint reception circuit according to the present invention for achieving the above purpose are its composition: in a satellite broadcast joint reception circuit for receiving satellite broadcasts through a jointly used central antenna and distributing them to the public service area, in the satellite broadcast received through the central antenna, each subscriber selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and a unique clock of each subscriber, frequency-modulates each channel in the microwave band, and combines and outputs them, and after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the channel frequencies of the microwave frequency-modulated composition output combined and output by the transmitting means, a receiving means is provided with a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to the satellite receiver. Kang at 2:

Asserted Claims	Kang
	At this time, the transmission circuit (100) receives vertical polarization (V) and horizontal polarization (H) satellite broadcasts through two common antenna (ANT1, ANT2), respectively, and then a matrix(110) that distributes satellites signals as many as the number of subscribers is connected to a tuning unit (120 [] 170) that has a unique clock of each subscriber and selects a predetermined channel according to the channel selection data (DT) output from each subscriber. Kang at 2: And, the first tuning unit (120) of the transmission circuit (100) is composed of a mixer (121) that mixes and outputs the frequencies of satellite broadcasting output from the matrix (110) of generator frequencies corresponding to the selected channel, a Phase Locked Loop (hereinafter referred to as PLL) (122) that always keeps the signal frequency of the output constant according to the channel selection data (DT) and a unique clock (CLK1) of each subscriber, a generator (123) that generates according to the output of the PLL (122) and outputs it the mixer (121), and a filter (124) that passes only a predetermined frequency among frequencies output from the mixer (121). Kang at 3: In addition, the transmission circuit (100) is provided with a control unit (195) for outputting channel selection data (DT) output from each subscriber, a unique clock (CLK1 [] CLK6) and error data to the tuning units (120 [] 170) through bidirectional communication with the reception circuit (200). Kang at 3: At this time, the first subscriber circuit (210) is composed of a tuning unit (211) that converts the frequency corresponding to the channel selection data value (DT) output from the first subscriber circuit (210) among the frequencies output from the transmission circuit (100) into an intermediate frequency and outputs the converted frequency to the satellite

Asserted Claims	Kang
	receiver (217) and an RF modem (218) for outputting the channel selection data (DT) to the control unit (195) of the transmission circuit (100) through the tuning unit (211) according to the channel selection in the satellite receiver (217). Kang at 3: Here, the tuning unit (211) is composed of a divider (212) for receiving a satellite signal transmitted through the divider (190) of the transmission circuit (100) or for outputting the channel selection data output from the RF modem (218) to the transmission circuit (100), a mixer (213) that mixes and outputs the generator frequency corresponding to the selected channel and the satellite broadcast frequency output through the divider (212), a PLL (214) that always maintains a constant signal frequency of an output according to the channel selection data (DT) output from the above RF modem (218) and a unique clock (CLK1) of each subscriber, a generator (215) that generates according to the output of the PLL (214) and outputs it to the mixer (213), and a SAW filter (216) that passes only a predetermined frequency among the frequencies output from the mixer (213). Kang at 4: At this time, taking each subscriber as an example, when the first subscriber of the first subscriber circuit (210) of the reception circuit (200) selects a channel through the satellite receiver (217), the channel data (DT) and the unique clock (CLK1) of the first subscriber are transmitted to the RF modem of the control unit (195) of the reception circuit (100) through the RF modem (210). Kang at 4: Also, the RF modem of the control unit (195) outputs the channel data (DT) and the unique clock (CLK1) of the first subscriber to the PLL (122) of the tuning unit (120) of the first subscriber, and the PLL (122) maintains a constant signal frequency of the output

Asserted Claims	Kang
	according to the channel selection data (DT) and the unique clock (CLK1) and outputs the output to the generator (123). Kang at 4: In this case, taking the first subscriber as an example, when an error occurs in the first subscriber circuit (210) of the RF modem (218) of the tuning unit (211) of the first subscriber circuit (210), the error is transmitted, and when a channel is selected, the channel selection data (DT) is transmitted to the RF modem of the control unit (195) of the transmission circuit (100) through the divider (212) together with the first subscriber's unique clock (CLK1). Kang at 5: Meanwhile, when the satellite receiver (217) of the first subscriber circuit (210) selects a channel, the channel selection data is output to the RF modem (218) through the signal input/output terminal (I/O), and the RF modem (218) outputs the channel selection data (DT) and the clock (CLK1) to the control unit (195) of the transmission circuit (100) and the PLL (214) of the first subscriber circuit (210) of the reception circuit (200). Kang at 5: The PLL (214) maintains a constant output signal frequency according to the channel selection data (DT) and the clock (CLK1) of the first subscriber and outputs it to the generator (215). Kang at 5: In other words, when a predetermined number of channel frequencies are combined and output in the transmission circuit (100), only the frequency of the channel selected by the

Asserted Claims	Kang
	first subscriber based on the channel data (DT) and the clock (CLK1) selected by the first subscriber is output through the mixer (213). To the extent Kang does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Kang alone or it would have been obvious to combine Kang with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
11. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network.	Kang discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network. *See* claim 10, *supra*. *See, e.g.*: Kang at Abstract: A satellite broadcast joint reception circuit advantageous for transmitting to a small number of subscribers through a joint reception system line after receiving and distributing satellite broadcast through a joint antenna is posted. This is composed of a transmission circuit that selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and the unique clock of each subscriber in the satellite broadcast received through the central antenna, modulates each FM in the UHF band, and combines them for output, and a reception circuit that, after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the predetermined number of UHF-FM modulated channel frequencies that are combined and output from the transmitting circuit, has a predetermined number of subscriber circuits for converting to satellite intermediate

Asserted Claims	Kang
	frequencies and outputting them to a satellite receiver. After selecting and receiving horizontal and vertical polarization satellite signals using a joint antenna, a predetermined channel is selected by each subscriber's tuning data and unique clock, modulated with UHF-FM, and transmitted through a joint reception system line, and each subscriber's receiver in the public area converts the UHF-FM signal of the channel selected by each subscriber into a satellite intermediate frequency. By doing so, paid channels and stereo are made possible, and as not as many demodulators and modulators as the number of satellite channels are required, the costs can be reduced and are suitable for a small system. Kang at 1: The features of the satellite broadcast joint reception circuit according to the present invention for achieving the above purpose are its composition: in a satellite broadcast joint reception circuit for receiving satellite broadcasts through a jointly used central antenna and distributing them to the public service area, in the satellite broadcast received through the central antenna, each subscriber selects a predetermined channel according to the channel selection data transmitted by each subscriber in the public service area and a unique clock of each subscriber, frequency-modulates each channel in the microwave band, and combines and outputs them, and after selecting the frequency of the corresponding channel according to the channel selection data and unique clock of each subscriber among the channel frequencies of the microwave frequency-modulated composition output combined and output by the transmitting means, a receiving means is provided with a predetermined number of subscriber circuits for converting to satellite intermediate frequencies and outputting them to the satellite receiver. Kang at 2: At this time, the transmission circuit (100) receives vertical polarization (V) and horizontal polarization (H) satellite broadcasts through two common antenna (ANT1, ANT2), respectively, and then a matrix(110) that distributes satellites signals as many as the number of subscribers is connected to a tuning unit (120 [] 170) that has a unique clock of

Asserted Claims	Kang
	each subscriber and selects a predetermined channel according to the channel selection data (DT) output from each subscriber. Kang at 2: And, the first tuning unit (120) of the transmission circuit (100) is composed of a mixer (121) that mixes and outputs the frequencies of satellite broadcasting output from the matrix (110) of generator frequencies corresponding to the selected channel, a Phase Locked Loop (hereinafter referred to as PLL) (122) that always keeps the signal frequency of the output constant according to the channel selection data (DT) and a unique clock (CLK1) of each subscriber, a generator (123) that generates according to the output of the PLL (122) and outputs it the mixer (121), and a filter (124) that passes only a predetermined frequency among frequencies output from the mixer (121). Kang at 3: In addition, the transmission circuit (100) is provided with a control unit (195) for outputting channel selection data (DT) output from each subscriber, a unique clock (CLK1 [] CLK6) and error data to the tuning units (120 [] 170) through bidirectional communication with the reception circuit (200). Kang at 3: At this time, the first subscriber circuit (210) is composed of a tuning unit (211) that converts the frequency corresponding to the channel selection data value (DT) output from the first subscriber circuit (210) among the frequencies output from the transmission circuit (100) into an intermediate frequency and outputs the converted frequency to the satellite receiver (217) and an RF modem (218) for outputting the channel selection data (DT) to the control unit (195) of the transmission circuit (100) through the tuning unit (211) according to the channel selection in the satellite receiver (217).

Asserted Claims	Kang
	Kang at 3: Here, the tuning unit (211) is composed of a divider (212) for receiving a satellite signal transmitted through the divider (190) of the transmission circuit (100) or for outputting the channel selection data output from the RF modem (218) to the transmission circuit (100), a mixer (213) that mixes and outputs the generator frequency corresponding to the selected channel and the satellite broadcast frequency output through the divider (212), a PLL (214) that always maintains a constant signal frequency of an output according to the channel selection data (DT) output from the above RF modem (218) and a unique clock (CLK1) of each subscriber, a generator (215) that generates according to the output of the PLL (214) and outputs it to the mixer (213), and a SAW filter (216) that passes only a predetermined frequency among the frequencies output from the mixer (213). Kang at 4: At this time, taking each subscriber as an example, when the first subscriber of the first subscriber circuit (210) of the reception circuit (200) selects a channel through the satellite receiver (217), the channel data (DT) and the unique clock (CLK1) of the first subscriber are transmitted to the RF modem of the control unit (195) of the reception circuit (100) through the RF modem (210). Kang at 4: Also, the RF modem of the control unit (195) outputs the channel data (DT) and the unique clock (CLK1) of the first subscriber to the PLL (122) of the tuning unit (120) of the first subscriber, and the PLL (122) maintains a constant signal frequency of the output according to the channel selection data (DT) and the unique clock (CLK1) and outputs the output to the generator (123). Kang at 4:

Asserted Claims	Kang
	In this case, taking the first subscriber as an example, when an error occurs in the first subscriber circuit (210) of the RF modem (218) of the tuning unit (211) of the first subscriber circuit (210), the error is transmitted, and when a channel is selected, the channel selection data (DT) is transmitted to the RF modem of the control unit (195) of the transmission circuit (100) through the divider (212) together with the first subscriber's unique clock (CLK1). Kang at 5: Meanwhile, when the satellite receiver (217) of the first subscriber circuit (210) selects a channel, the channel selection data is output to the RF modem (218) through the signal input/output terminal (I/O), and the RF modem (218) outputs the channel selection data (DT) and the clock (CLK1) to the control unit (195) of the transmission circuit (100) and the PLL (214) of the first subscriber circuit (210) of the reception circuit (200). Kang at 5: The PLL (214) maintains a constant output signal frequency according to the channel selection data (DT) and the clock (CLK1) of the first subscriber and outputs it to the generator (215). Kang at 5: In other words, when a predetermined number of channel frequencies are combined and output in the transmission circuit (100), only the frequency of the channel selected by the first subscriber based on the channel data (DT) and the clock (CLK1) selected by the first subscriber is output through the mixer (213). Kang at 2: At this time, the transmission circuit (100) receives vertical polarization (V) and horizontal polarization (H) satellite broadcasts through two common antenna (ANT1, ANT2), respectively, and then a matrix(110) that distributes satellites signals as many as the number of subscribers is connected to a tuning unit (120 [] 170) that has a unique clock of each subscriber and selects a predetermined channel according to the channel selection data (DT) output from each subscriber. Kang at 2:

Asserted Claims	Kang
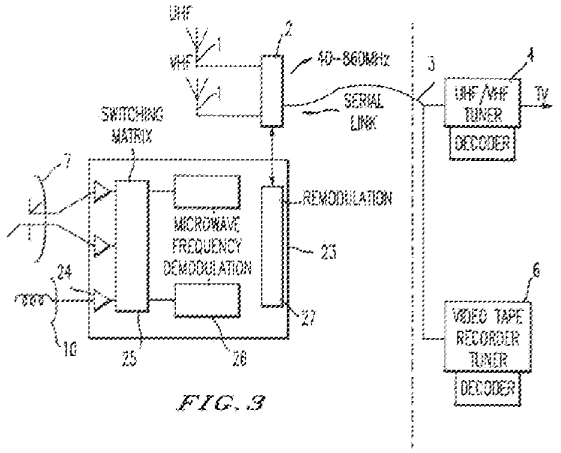
	And, the first tuning unit (120) of the transmission circuit (100) is composed of a mixer (121) that mixes and outputs the frequencies of satellite broadcasting output from the matrix (110) of generator frequencies corresponding to the selected channel, a Phase Locked Loop (hereinafter referred to as PLL) (122) that always keeps the signal frequency of the output constant according to the channel selection data (DT) and a unique clock (CLK1) of each subscriber, a generator (123) that generates according to the output of the PLL (122) and outputs it the mixer (121), and a filter (124) that passes only a predetermined frequency among frequencies output from the mixer (121). Kang at 3: In addition, the transmission circuit (100) is provided with a control unit (195) for outputting channel selection data (DT) output from each subscriber, a unique clock (CLK1 [] CLK6) and error data to the tuning units (120 [] 170) through bidirectional communication with the reception circuit (200). Kang at 3: At this time, the first subscriber circuit (210) is composed of a tuning unit (211) that converts the frequency corresponding to the channel selection data value (DT) output from the first subscriber circuit (210) among the frequencies output from the transmission circuit (100) into an intermediate frequency and outputs the converted frequency to the satellite receiver (217) and an RF modem (218) for outputting the channel selection data (DT) to the control unit (195) of the transmission circuit (100) through the tuning unit (211) according to the channel selection in the satellite receiver (217). Kang at 3: Here, the tuning unit (211) is composed of a divider (212) for receiving a satellite signal transmitted through the divider (190) of the transmission circuit (100) or for outputting the channel selection data output from the RF modem (218) to the transmission circuit (100), a

Asserted Claims	Kang
	mixer (213) that mixes and outputs the generator frequency corresponding to the selected channel and the satellite broadcast frequency output through the divider (212), a PLL (214) that always maintains a constant signal frequency of an output according to the channel selection data (DT) output from the above RF modem (218) and a unique clock (CLK1) of each subscriber, a generator (215) that generates according to the output of the PLL (214) and outputs it to the mixer (213), and a SAW filter (216) that passes only a predetermined frequency among the frequencies output from the mixer (213). Kang at 4: At this time, taking each subscriber as an example, when the first subscriber of the first subscriber circuit (210) of the reception circuit (200) selects a channel through the satellite receiver (217), the channel data (DT) and the unique clock (CLK1) of the first subscriber are transmitted to the RF modem of the control unit (195) of the reception circuit (100) through the RF modem (210). Kang at 4: Also, the RF modem of the control unit (195) outputs the channel data (DT) and the unique clock (CLK1) of the first subscriber to the PLL (122) of the tuning unit (120) of the first subscriber, and the PLL (122) maintains a constant signal frequency of the output according to the channel selection data (DT) and the unique clock (CLK1) and outputs the output to the generator (123). Kang at 4: In this case, taking the first subscriber as an example, when an error occurs in the first subscriber circuit (210) of the RF modem (218) of the tuning unit (211) of the first subscriber circuit (210), the error is transmitted, and when a channel is selected, the channel selection data (DT) is transmitted to the RF modem of the control unit (195) of the

Asserted Claims	Kang
	transmission circuit (100) through the divider (212) together with the first subscriber's unique clock (CLK1). Kang at 5: Meanwhile, when the satellite receiver (217) of the first subscriber circuit (210) selects a channel, the channel selection data is output to the RF modem (218) through the signal input/output terminal (I/O), and the RF modem (218) outputs the channel selection data (DT) and the clock (CLK1) to the control unit (195) of the transmission circuit (100) and the PLL (214) of the first subscriber circuit (210) of the reception circuit (200). Kang at 5: The PLL (214) maintains a constant output signal frequency according to the channel selection data (DT) and the clock (CLK1) of the first subscriber and outputs it to the generator (215). Kang at 5: In other words, when a predetermined number of channel frequencies are combined and output in the transmission circuit (100), only the frequency of the channel selected by the first subscriber based on the channel data (DT) and the clock (CLK1) selected by the first subscriber is output through the mixer (213). To the extent Kang does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Kang alone or it would have been obvious to combine Kang with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

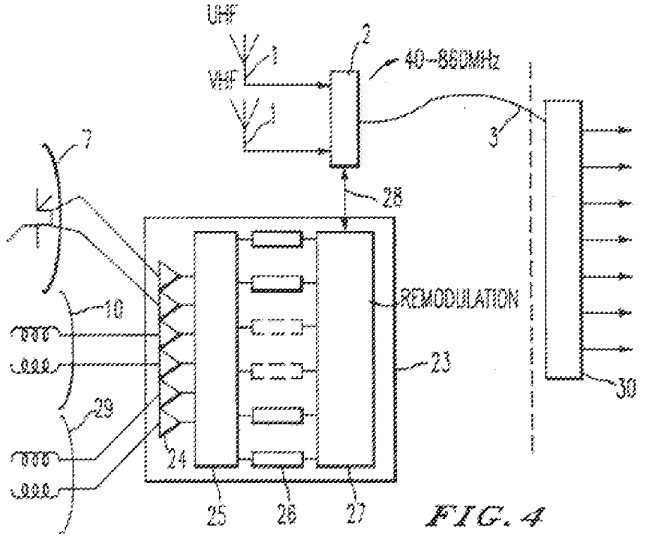
Exhibit B9 – Mutzig Invalidity Claim Chart

INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Mutzig

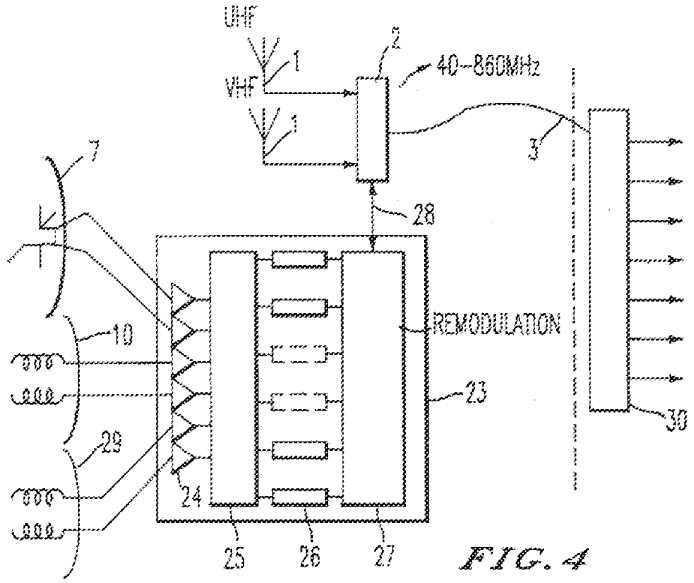


U.S. Patent No. 5,276,904 ("Mutzig") issued on January 4, 1994. Mutzig therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(a), (b) and/or (e). For the reasons listed below, Mutzig invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Mutzig
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Mutzig discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*: Mutzig at 2:55-58: In this figure, as in all of the others except for FIGS. 8 and 9, the vertical dotted line separates the external unit, to the left of the figure, from the internal unit, to the right.

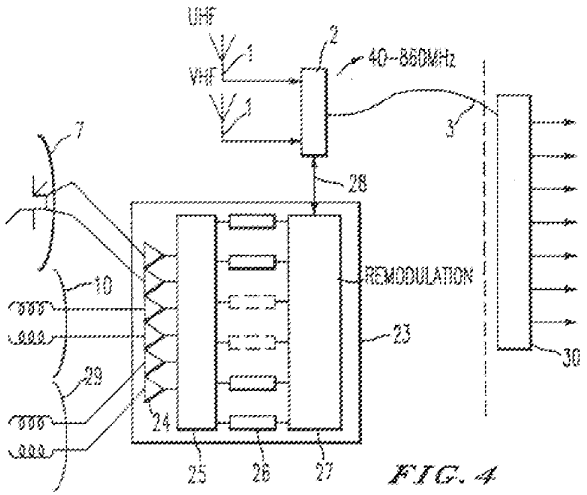


[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.



Page 2036 of 4862

Asserted Claims	Mutzig
	Mutzig at 3:58-4:4: The invention proposes a solution to the multiplication of converters in the external unit and of the link cables to the internal unit, by adapting a microwave frequency head, located in an external unit, integrated with the antenna for example. This receiving head comprises a multi-band converter, operating at a frequency which is programmed by control from the internal unit and a single receiving head can then process 20 to 40 channels. But furthermore, the received signals are demodulated and processed on the spot by the microwave head which supplies signals which are remodulated in amplitude modulation, which allows them to be applied to the multiplexer of VHF-UHF terrestrial microwave link receiving antennas, and the use of the existing single, 40-860 MHz link cable. Mutzig at 4:13-20: More precisely, the invention comprises a system for receiving TV signals retransmitted by satellites, intended for the transmission of at least one channel from among a plurality of channels from at least one antenna, in an external unit, to at least one receiver in an internal unit, this system being characterized in that it comprises, in an external unit, a microwave frequency head which comprises at least: Mutzig at 4:57-5:7: FIG. 3 shows the system for receiving signals retransmitted by satellites according to the invention. The external unit for receiving terrestrial signals comprising the VHF/UHF antennas 1, the multiplexer 2 and the link cable 3 to the internal unit is assumed to already exist, because it is the most common case. If this is not the case, it suffices to install a conventional link cable 3, adapted to 40-860 MHz amplitude modulated signals. This system of receiving satellite signals is based on a microwave frequency head 23, interposed between the parabolic antenna or antennas 7 and 10, and the multiplexer 2 of the existing installation. The number and type of the parabolic antennas does not limit the extent of the invention and, if there is no multiplexer 2, the link cable 3 is connected directly to the



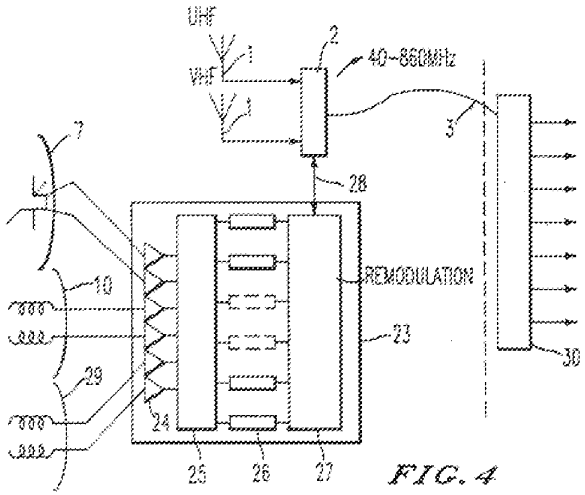
Asserted Claims	Mutzig
	microwave frequency head since one of its purposes is to process the satellite signals in order to make them compatible with the terrestrial signals and pass through the same cable. Mutzig at Fig. 3:  FIG. 3 Mutzig at 5:8-32: The structure of the microwave frequency head 23, which will be described in detail below comprises: a series of low noise amplifiers 24 each of which receives on its input the signal coming from a parabolic antenna, or from an antenna element, according to the polarization of the signal, a switching matrix allowing the selection of the channel or channels chosen from among those transmitted by the satellite or satellites; this matrix allows the choice of the program from several simultaneously transmitted channels, at least two microwave frequency demodulators 26, a remodulation circuit 27, which converts the FM modulated signals in baseband, 0-6 MHz for example coming from demodulators 26, into amplitude modulated signals in the 40-860 MHz band a 40-860 MHz downward link

Asserted Claims	Mutzig
	to the internal unit, an upward link using the same physical medium 3-28, allowing the transmission of the digital data necessary for the selection of the satellite or satellites and of the channels to be demodulated. It also allows a decision to be made on the re-modulation frequency plan, which depends on the microwave channels already received locally. Mutzig at 5:39-45: On the contrary, FIG. 4 shows the advantage of the microwave frequency head according to the invention for simultaneously using a large number of channels transmitted by satellites. The number of amplifiers 24 is adapted to the number and to the types of parabolic antennas 7, 10, 29 and to the number of corresponding channels. Mutzig at Fig. 4:

Asserted Claims	Mutzig
	 FIG. 4 To the extent Mutzig does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Mutzig alone or it would have been obvious to combine Mutzig with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[a] a gateway in communication with the ODU and at least one set top box (STB);	Mutzig discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Mutzig at 6:5-13:

Asserted Claims	Mutzig
	The output signals from the head all use the single link cable 3, and are applied by the distributor 30, in the internal unit, to the various receiving devices, either television or telecommunications, each of which decodes the information corresponding to a channel. By way of example, the microwave frequency head according to the invention allows the simultaneous use of up to 20 to 40 channels, in collective reception for a building or a telecommunications center. Mutzig at Fig. 4:  FIG. 4 To the extent Mutzig does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Mutzig alone or it would have been obvious to combine Mutzig with one or more prior

Asserted Claims	Mutzig
	art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information;	Mutzig discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*: Mutzig at 4:14-20: More precisely, the invention comprises a system for receiving TV signals retransmitted by satellites, intended for the transmission of at least one channel from among a plurality of channels from at least one antenna, in an external unit, to at least one receiver in an internal unit, this system being characterized in that it comprises, in an external unit, a microwave frequency head which comprises at least: Mutzig at 5:10-13: a series of low noise amplifiers 24 each of which receives on its input the signal coming from a parabolic antenna, or from an antenna element, according to the polarization of the signal, Mutzig at 5:25-31: an upward link using the same physical medium 3+28, allowing the transmission of the digital data necessary for the selection of the satellite or satellites and of the channels to be demodulated. It also allows a decision to be made on the re-modulation frequency plan, which depends on the microwave channels already received locally.



Asserted Claims	Mutzig
	Mutzig at Fig. 4:  FIG. 4 Mutzig at 5:47-55: But in this case, the switching matrix 25 of FIG. 3 is replaced by a power distributor 25' which transmits all of the channels to a plurality of microwave frequency demodulators 26. This constitutes a solution for the collective service of a building, by means of which a large number of users can each receive a different channel, since all of the channels are demodulated simultaneously. This service is known by the abbreviation SMATV, standing for "Satellite Master Antenna TV". Mutzig at 6:43-52: The converter and the RF/IF module are both controlled from a quartz crystal 37 which, via a synthesizer 38, controls an oscillator 39. The synthesizer 38 is an assembly which is

Asserted Claims	Mutzig
	known and available on the market 50 55 65 and is controlled on its input 40 by digital data transmit ted by the link cable 3, and it allows the selection of a channel, or of N channels from among M channels, by choosing an appropriate frequency. The oscillator 39 directly controls the mixer 34, of the RF/IF module, for example at 2.3 GHz. Mutzig at 8:28-36: But a regulated power supply 54 injects a DC current, Smoothed by the LC element 55, onto this same cable 3; the digital data necessary for programming the microwave frequency head according to the invention, coming from the internal unit, are applied to a shaping circuit 56 and then to a multiplexing circuit 57, which distributes them to the switching matrix 25, to the direct demodulation converters 26 and to the MABLR remodulator 27. To the extent Mutzig does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Mutzig alone or it would have been obvious to combine Mutzig with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Mutzig discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*: Mutzig at 6:29-35: The converter comprises a low noise input amplifier 31 which receives the signals from the antenna 7, a mixer 32 and an output amplifier 33. The converter is controlled by a multi-band oscillator which will be described later. This converter allows the conversion of the entire frequency band of a satellite into a frequency range of 0.95 to 1.70 GHz.

Asserted Claims	Mutzig
	Mutzig at 7:27-41: It is therefore an advantage of the invention that the signal is remodulated, as shown in FIG. 7. The modulator 48 receives the signal in base band, 0-6MHz, coming from the filter 47, and applies residual side band amplitude modulation (MABLR) to it and it sends, through the link cable 3, signals at 40-860 MHz which are insensitive to interference. This allows the system to be compatible with the existing standard links since the microwave frequency head according to the invention supplies amplitude modulated signals in the 40-860 MHz band, like the conventional VHF-UHF antennas. Furthermore, in the case of a simultaneous reception a single link suffices for transmitting several programs, in 8 MHz steps for example. To the extent Mutzig does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Mutzig alone or it would have been obvious to combine Mutzig with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[d] a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal;	Mutzig discloses, explicitly and/or inherently, a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal. *See, e.g.*: Mutzig at 4:14-20: More precisely, the invention comprises a system for receiving TV signals retransmitted by satellites, intended for the transmission of at least one channel from among a plurality of channels from at least one antenna, in an external unit, to at least one receiver in an internal unit, this system being characterized in that it comprises, in an external unit, a microwave frequency head which comprises at least:

9[e] wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific	Mutzig discloses, explicitly and/or inherently, wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs. *See, e.g.*:

Asserted Claims	Mutzig
programs, and distributes the programs over a digital local area network (LAN) to STBs.	Mutzig at 8:38-55: An advantage of the microwave frequency head according to the invention is that it processes the signals retransmitted by different satellites and routes them through a 40-860 MHz downward link which is none other than the existing VHF/UHF antenna cable. This is due to the remodulation in MABLR amplitude modulation. However, the microwave frequency head can also be used with receivers fitted with a "satellite" input which receives the signals in the satellite intermediate band 950-1700 MHz. In this case, it suffices to eliminate the FM demodulation, which is carried out by means of a switch in the link 46, and to output before the MABLR remodulation. But in this case the downward link must pass the 40-1700 MHz band. The programming of the microwave frequency head is of course adapted to allow the remote control either of the demodulation of a channel, or of the conversion into satellite intermediate band. To the extent Mutzig does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Mutzig alone or it would have been obvious to combine Mutzig with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
10. The signal distribution system of claim 9 wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output.	Mutzig discloses, explicitly and/or inherently, wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output. *See* claim 9, *supra*. To the extent Mutzig does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Mutzig alone or it would have been obvious to combine Mutzig with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

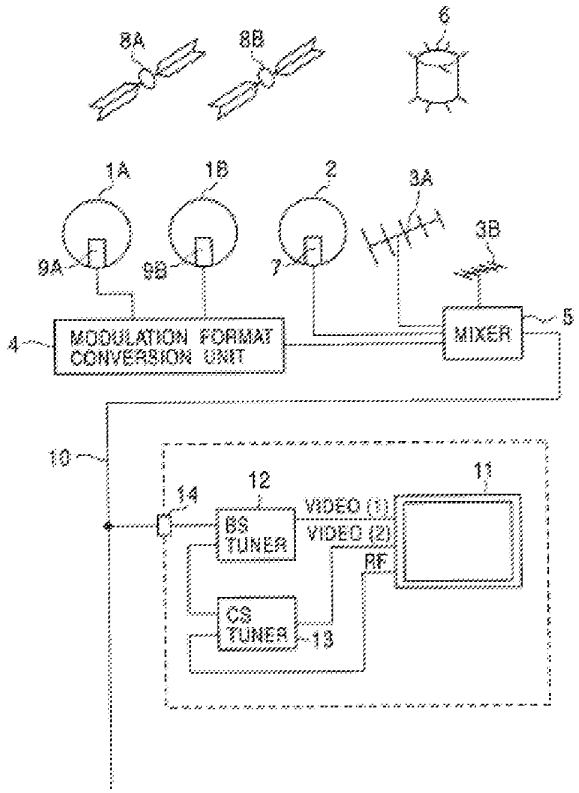
Asserted Claims	Mutzig
11. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network.	Mutzig discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network. *See* claim 10, *supra*. To the extent Mutzig does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Mutzig alone or it would have been obvious to combine Mutzig with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
12. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network.	Mutzig discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network. *See* claim 10, *supra*. To the extent Mutzig does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Mutzig alone or it would have been obvious to combine Mutzig with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Oishi

U.S. Patent No. 7,263,713 ("Oishi") was filed on February 26, 2001 and issued on August 28, 2007. Oishi issued from U.S. Patent Application Pub. No. 2002/0056140, which was published on May 9, 2002. Oishi therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(e).[2] For the reasons listed below, Oishi invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Oishi
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Oishi discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*:

[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.



[2] In the event Plaintiff cannot claim the benefit of the priority date of the provisional applications, the Oishi patent application would also qualify as prior art under (pre-AIA) 35 U.S.C. § 102(a).

Asserted Claims	Oishi
	Oishi at 1:9–19: The present invention generally relates to television signal distributor apparatuses, receiver apparatuses, and television signal transmission systems and methods. More specifically, the present invention relates to a television signal distributor apparatus, a receiver apparatus, a television signal transmission system and method, which are particularly suitable for implementing a small-scale television signal distribution network in which television signals received via a master antenna provided on the rooftop at collective housing, such as an apartment building, are delivered to each household via a cable. Oishi at 3:22–30: Accordingly, it is an object of the present invention to provide a television signal distribution apparatus, a receiver apparatus, and a television signal transmission system and method, which allows, without implementing large-scale works, terrestrial broadcasting signals in the VHF and UHF bands, the BS intermediate frequency signals, and CS intermediate frequency signals of a CS broadcasting service which employs two or more satellites to be multiplexed for transmission to each household via a single cable. Oishi at 3:31–53: To this end, the present invention provides a television signal transmission system including a television signal distributor apparatus which delivers signals received via a master antenna to each household via a cable; and at least one receiver apparatus provided in each household. The television signal distributor apparatus includes a modulation format converting unit for converting the modulation format of received CS broadcast signals to thereby accommodate the signals in a narrower bandwidth, and for frequency-shifting the signals accommodated in the narrower bandwidth into a vacant frequency band; and a mixing unit for mixing for transmission via the cable the frequency-shifted signals accommodated in said narrower bandwidth with other type or types of received broadcast signals. The at least one receiver apparatus includes a receiving unit for receiving CS broadcast signals which have undergone conversion of modulation format so as to be

Asserted Claims	Oishi
	accommodated in a narrower bandwidth and which have then been frequency-shifted into a vacant frequency band; a demodulating unit for demodulating the received signals in accordance with the modulation format after conversion; and a decoding unit for decoding the output from the demodulating unit to obtain video signals and audio signals. Oishi at 3:54–4:3: In accordance with the present invention, the modulation format of CS intermediate frequency signals is converted, for example, from QPSK to 64-QAM; thus, CS broadcasting signals from each transponder, having a bandwidth of, for example, 27 MHz, are accommodated in a bandwidth of, for example, 6 MHz, which is equivalent to a single channel for terrestrial broadcasting. The CS signals which have undergone conversion of the modulation format are frequency-shifted into a vacant channel in the VHF band or the UHF band. The frequency-shifted CS signals are multiplexed with BS intermediate frequency signals and terrestrial broadcasting signals for transmission to each household via a single cable. Accordingly, signals for a CS broadcasting service, even if provided via two or more satellites, can be transmitted to each household via a single cable together with signals for a BS broadcasting service and terrestrial broadcasting signals. Oishi at 4:57–5:9: FIG. 3 shows the frequency allocation of signals transmitted via a cable. Referring to FIG. 3, A 1 (90 MHz to 108 MHz) is the VHF low band, A2 (108 MHz to 170 MHz) is the VHF mid band, A3 (170 MHz to 222 MHz) is the VHF high band, A4 (222 MHz to 470 MHz) is the VHF super high band, A5 (470 MHz to 770 MHz) is the UHF band, and A6 (1035 MHz to 1335 MHz) is a band for intermediate frequency signals of BS broadcasting signals. Currently, the VHF low band A1 and the VHF high band A3 are used for VHF terrestrial television broadcasting, and the UHF band A5 is used for UHF terrestrial television broadcasting. The VHF mid band A2 and the VHF super high band A4 are allocated for CATV (Cable Television); and therefore, the bands are vacant where CATV service is not used. The BS broadcasting signals are broadcast on electromagnetic waves in the 12-GHz band. When received via a parabola antenna, the BS broadcasting signals are

Asserted Claims	Oishi
	converted into intermediate frequency signals in the 1-GHz band in an LNB (Low Noise Block Down Converter) provided in association with the parabola antenna. Oishi at 5:10–32: CS broadcasting signals are also broadcast on electromagnetic waves in the 12-GHz band, and include vertically polarized signals and horizontally polarized signals. In the case of a CS service which employs two satellites, signals from one satellite and signals from the other respectively includes vertical polarization signals and horizontal polarization signals. For example, the Japanese SKY PerfecTV employs two satellites for its broadcasting service, and signals from each of the two satellites includes vertically polarized signals and horizontally polarized signals. The CS broadcasting signals in the 12-GHz band are converted into intermediate frequency signals in the 1-GHz band in an LNB provided in association with a parabola antenna. In order to accommodate the CS broadcasting signals, there are provided four bands B 1, B2, B3, and B4 corresponding to vertically polarized signals and horizontally polarized signals from each of the two satellites. The bands B1 to B4 overlap the band A6 for intermediate frequency signals of BS broadcasting signals. Thus, it is not feasible to simply mix CS intermediate frequency signals, BS intermediate frequency signals, and terrestrial television broadcasting signals in the VHF and UHF bands and to deliver all these signals to each household via a single cable. Oishi at 6:28–34: The CS parabola antennas 1A and 1B receive signals transmitted from two communications satellites 8A and 8B. The parabola antennas 1A and 1B are provided with LNBs 9A and 9B, respectively. The LNBs 9A and 9B converts CS broadcasting signals in the 12-GHz band into intermediate frequency signals. The outputs of the LNBs 9A and 9B are fed to a modulation format conversion unit 4. Oishi at 6:43–48: The BS parabola antenna 2 receives signals from a broadcasting satellite 6. The parabola antenna 2 is provided with an LNB 7. The LNB 7 converts signals in the 12-GHz band

Asserted Claims	Oishi
	received by the parabola antenna 2 into intermediate frequency signals in the 1-GHz band. The output of the LNB 7 is fed to the mixer 5. Oishi at 6:49–51: The antennas 3A and 3B receive terrestrial broadcasting signals in the VHF and UHF bands. The outputs of the antennas 3A and 3B are fed to the mixer 5. Oishi at 6:52–54: The mixer 5 mixes the output from the modulation format conversion unit 4, the output from the LNB 7, and the output from the antennas 3A and 3B. Oishi at 7:43–50: FIG. 5 shows the construction of the modulation format conversion unit 4. As described above, the modulation format conversion unit 4 receives CS intermediate frequency signals from the LNBs 9A and 9B provided in association with the parabola antennas 1A and 1B, converts the modulation format of the CS intermediate frequency signals from QPSK to 64-QAM, and frequency-shifts the signals into a vacant channel in the VHF band or the UHF band. Oishi at 7:60–65: Referring to FIG. 5, CS intermediate frequency signals output from the LNBs 9A and 9B of the parabola antennas 1A and 1B are fed to an input terminal 21. The signals input to the input terminal 21 are fed to each tuner circuit 22 of the modulation circuit 4A, 4B, 4C, etc. The tuner circuit 22 selects signals on a desired carrier wave. Oishi at Fig. 4:

Asserted Claims	Oishi
	FIG. 4  To the extent Oishi does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Oishi alone or it would have been obvious to combine Oishi with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Asserted Claims	Oishi
9[a] a gateway in communication with the ODU and at least one set top box (STB);	Oishi discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Oishi at 3:22–30: Accordingly, it is an object of the present invention to provide a television signal distribution apparatus, a receiver apparatus, and a television signal transmission system and method, which allows, without implementing large-scale works, terrestrial broadcasting signals in the VHF and UHF bands, the BS intermediate frequency signals, and CS intermediate frequency signals of a CS broadcasting service which employs two or more satellites to be multiplexed for transmission to each household via a single cable. Oishi at 3:31–53: To this end, the present invention provides a television signal transmission system including a television signal distributor apparatus which delivers signals received via a master antenna to each household via a cable; and at least one receiver apparatus provided in each household. The television signal distributor apparatus includes a modulation format converting unit for converting the modulation format of received CS broadcast signals to thereby accommodate the signals in a narrower bandwidth, and for frequency-shifting the signals accommodated in the narrower bandwidth into a vacant frequency band; and a mixing unit for mixing for transmission via the cable the frequency-shifted signals accommodated in said narrower bandwidth with other type or types of received broadcast signals. The at least one receiver apparatus includes a receiving unit for receiving CS broadcast signals which have undergone conversion of modulation format so as to be accommodated in a narrower bandwidth and which have then been frequency-shifted into a vacant frequency band; a demodulating unit for demodulating the received signals in

Asserted Claims	Oishi
	accordance with the modulation format after conversion; and a decoding unit for decoding the output from the demodulating unit to obtain video signals and audio signals. Oishi at 7:10–12: The terrestrial broadcasting signals are fed from the terminal 14, through the BS tuner 12 and the CS tuner 13, to an RF input terminal of the television receiver 11. To the extent Oishi does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Oishi alone or it would have been obvious to combine Oishi with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information;	Oishi discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*: Oishi at 1:9–19: The present invention generally relates to television signal distributor apparatuses, receiver apparatuses, and television signal transmission systems and methods. More specifically, the present invention relates to a television signal distributor apparatus, a receiver apparatus, a television signal transmission system and method, which are particularly suitable for implementing a small-scale television signal distribution network in which television signals received via a master antenna provided on the rooftop at collective housing, such as an apartment building, are delivered to each household via a cable.

Asserted Claims	Oishi
	Oishi at 3:22–30: Accordingly, it is an object of the present invention to provide a television signal distribution apparatus, a receiver apparatus, and a television signal transmission system and method, which allows, without implementing large-scale works, terrestrial broadcasting signals in the VHF and UHF bands, the BS intermediate frequency signals, and CS intermediate frequency signals of a CS broadcasting service which employs two or more satellites to be multiplexed for transmission to each household via a single cable. Oishi at 3:31–53: To this end, the present invention provides a television signal transmission system including a television signal distributor apparatus which delivers signals received via a master antenna to each household via a cable; and at least one receiver apparatus provided in each household. The television signal distributor apparatus includes a modulation format converting unit for converting the modulation format of received CS broadcast signals to thereby accommodate the signals in a narrower bandwidth, and for frequency-shifting the signals accommodated in the narrower bandwidth into a vacant frequency band; and a mixing unit for mixing for transmission via the cable the frequency-shifted signals accommodated in said narrower bandwidth with other type or types of received broadcast signals. The at least one receiver apparatus includes a receiving unit for receiving CS broadcast signals which have undergone conversion of modulation format so as to be accommodated in a narrower bandwidth and which have then been frequency-shifted into a vacant frequency band; a demodulating unit for demodulating the received signals in accordance with the modulation format after conversion; and a decoding unit for decoding the output from the demodulating unit to obtain video signals and audio signals. Oishi at 4:45–56: In accordance with the present invention, CS broadcasting signals from each transponder received via a master antenna undergo conversion of the modulation format so that the signals are accommodated in a narrower bandwidth. The signals accommodated in the

Asserted Claims	Oishi
	narrower bandwidth are then frequency-shifted into a vacant channel in the VHF band or the UHF band. This eliminates the need to provide an additional band for the CS broadcasting signals; thus, the CS broadcasting signals, even if serviced by two or more satellites, can be delivered to each household via a single cable together with terrestrial television broadcasting signals and BS broadcasting signals. Oishi at 6:57–60: Each household is provided with a television receiver 11, a BS tuner 12, and a CS tuner 13 compatible with the television signal transmission system. The television receiver 11 has two external video/audio input terminals. Oishi at 6:61–67: Of the signals transmitted via the cable 10, the BS intermediate frequency signals are fed to the BS tuner 12 via the terminal 14. The BS tuner 12 demodulates the BS intermediate frequency signals to obtain video signals and audio signals, for example, in the NTSC format. The output of the BS tuner 12 is fed to one of the external video/audio input terminals Video(1) of the television receiver 11. Oishi at 7:1–9: The CS intermediate frequency signals which have undergone conversion of the modulation format and which have been frequency-shifted are fed from the terminal 14 via an RF through circuit and a distributor circuit of the BS tuner 12 to the CS tuner 13. The CS tuner 13 demodulates the CS intermediate frequency signals to obtain video signals and audio signals, for example, in the NTSC format. The output of the CS tuner 12 is fed to the other external video/audio input terminal Video(2) of the television receiver 11. Oishi at 7:10–12:

Asserted Claims	Oishi
	The terrestrial broadcasting signals are fed from the terminal 14, through the BS tuner 12 and the CS tuner 13, to an RF input terminal of the television receiver 11. Oishi at 7:13–23: As described above, in the television signal transmission system shown in FIG. 4, the modulation format conversion unit 4 converts the modulation format of the CS intermediate frequency signals so as to accommodate the signals in a narrower bandwidth, and frequency-shifts the signals into a vacant band in the VHF band or in the UHF band. Then, the output of the modulation format conversion unit 4 is multiplexed in the mixer 5 with the BS intermediate frequency signals and terrestrial broadcasting signals in the VHF and UHF bands, so that the mixed signals are transmitted to each household via the cable 10. Oishi at 7:24–33: In each household, the BS tuner 12 demodulates the BS intermediate frequency signals, and outputs corresponding video and audio signals to the external video/audio input terminal Video(1) of the television receiver 11. The CS tuner 13 decodes the CS intermediate frequency signals and outputs corresponding video and audio signals to the external video/audio input terminal Video(2) of the television receiver 11. The terrestrial broadcasting signals in the VHF and UHF bands are input to the RF input terminal of the television receiver 11. Oishi at 7:34–42: Accordingly, when the RF input is selected, the television receiver 11 reproduces the picture and sound of terrestrial television broadcasting in the VHF and UHF bands. When the external video/audio input Video(1) is selected, the television receiver 11 reproduces the picture and sound of BS broadcasting based on the output of the BS tuner 12. When the external video/audio input Video(2) is selected, the television receiver 11 reproduces the picture and sound of CS broadcasting based on the output of the CS tuner 13.

Asserted Claims	Oishi
	Oishi at 9:34–42: The setting for the CS tuner 13 is made via an operation unit 62, and the setting is displayed in a display unit 63. The control circuit 61 is provided with a frequency conversion table 64. The frequency conversion table 63 shows the correspondence between the frequency information of the satellite system shown in NIT (Network Information Table) and the frequency information of the transmission system of the signals transmitted via the cable 10. The frequency conversion table 64 is referenced when the receiving frequency is set in the tuner circuit 43. To the extent Oishi does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Oishi alone or it would have been obvious to combine Oishi with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Oishi discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*: Oishi at 3:22–30: Accordingly, it is an object of the present invention to provide a television signal distribution apparatus, a receiver apparatus, and a television signal transmission system and method, which allows, without implementing large-scale works, terrestrial broadcasting signals in the VHF and UHF bands, the BS intermediate frequency signals, and CS intermediate frequency signals of a CS broadcasting service which employs two or more satellites to be multiplexed for transmission to each household via a single cable.

Asserted Claims	Oishi
	Oishi at 3:31–53: To this end, the present invention provides a television signal transmission system including a television signal distributor apparatus which delivers signals received via a master antenna to each household via a cable; and at least one receiver apparatus provided in each household. The television signal distributor apparatus includes a modulation format converting unit for converting the modulation format of received CS broadcast signals to thereby accommodate the signals in a narrower bandwidth, and for frequency-shifting the signals accommodated in the narrower bandwidth into a vacant frequency band; and a mixing unit for mixing for transmission via the cable the frequency-shifted signals accommodated in said narrower bandwidth with other type or types of received broadcast signals. The at least one receiver apparatus includes a receiving unit for receiving CS broadcast signals which have undergone conversion of modulation format so as to be accommodated in a narrower bandwidth and which have then been frequency-shifted into a vacant frequency band; a demodulating unit for demodulating the received signals in accordance with the modulation format after conversion; and a decoding unit for decoding the output from the demodulating unit to obtain video signals and audio signals. Oishi at 3:54–4:3: In accordance with the present invention, the modulation format of CS intermediate frequency signals is converted, for example, from QPSK to 64-QAM; thus, CS broadcasting signals from each transponder, having a bandwidth of, for example, 27 MHz, are accommodated in a bandwidth of, for example, 6 MHz, which is equivalent to a single channel for terrestrial broadcasting. The CS signals which have undergone conversion of the modulation format are frequency-shifted into a vacant channel in the VHF band or the UHF band. The frequency-shifted CS signals are multiplexed with BS intermediate frequency signals and terrestrial broadcasting signals for transmission to each household via a single cable. Accordingly, signals for a CS broadcasting service, even if provided via two or more satellites, can be transmitted to each household via a single cable together with signals for a BS broadcasting service and terrestrial broadcasting signals.

Asserted Claims	Oishi
	Oishi at 4:45–56: In accordance with the present invention, CS broadcasting signals from each transponder received via a master antenna undergo conversion of the modulation format so that the signals are accommodated in a narrower bandwidth. The signals accommodated in the narrower bandwidth are then frequency-shifted into a vacant channel in the VHF band or the UHF band. This eliminates the need to provide an additional band for the CS broadcasting signals; thus, the CS broadcasting signals, even if serviced by two or more satellites, can be delivered to each household via a single cable together with terrestrial television broadcasting signals and BS broadcasting signals. Oishi at 4:57–5:9: FIG. 3 shows the frequency allocation of signals transmitted via a cable. Referring to FIG. 3, A 1 (90 MHz to 108 MHz) is the VHF low band, A2 (108 MHz to 170 MHz) is the VHF mid band, A3 (170 MHz to 222 MHz) is the VHF high band, A4 (222 MHz to 470 MHz) is the VHF super high band, A5 (470 MHz to 770 MHz) is the UHF band, and A6 (1035 MHz to 1335 MHz) is a band for intermediate frequency signals of BS broadcasting signals. Currently, the VHF low band A1 and the VHF high band A3 are used for VHF terrestrial television broadcasting, and the UHF band A5 is used for UHF terrestrial television broadcasting. The VHF mid band A2 and the VHF super high band A4 are allocated for CATV (Cable Television); and therefore, the bands are vacant where CATV service is not used. The BS broadcasting signals are broadcast on electromagnetic waves in the 12-GHz band. When received via a parabola antenna, the BS broadcasting signals are converted into intermediate frequency signals in the 1-GHz band in an LNB (Low Noise Block Down Converter) provided in association with the parabola antenna. Oishi at 6:17–27: FIG. 4 illustrates the overall construction of a television signal transmission system, as connected to associated systems, according to the embodiment of present invention. Referring to FIG. 4, there are shown parabola antennas 1A and 1B for receiving CS

Asserted Claims	Oishi
	broadcasting signals, a parabola antenna 2 for receiving BS broadcasting signals, and antennas 3A and 3B for receiving terrestrial broadcasting signals respectively in the VHF band and in the UHF band. The antennas 1A, 1B, 2, 3A, and 3B are master antennas, and are provided, for example, on the rooftop of an apartment building. Oishi at 6:28–34: The CS parabola antennas 1A and 1B receive signals transmitted from two communications satellites 8A and 8B. The parabola antennas 1A and 1B are provided with LNBs 9A and 9B, respectively. The LNBs 9A and 9B converts CS broadcasting signals in the 12-GHz band into intermediate frequency signals. The outputs of the LNBs 9A and 9B are fed to a modulation format conversion unit 4. Oishi at 6:43–48: The BS parabola antenna 2 receives signals from a broadcasting satellite 6. The parabola antenna 2 is provided with an LNB 7. The LNB 7 converts signals in the 12-GHz band received by the parabola antenna 2 into intermediate frequency signals in the 1-GHz band. The output of the LNB 7 is fed to the mixer 5. Oishi at 6:49–51: The antennas 3A and 3B receive terrestrial broadcasting signals in the VHF and UHF bands. The outputs of the antennas 3A and 3B are fed to the mixer 5. Oishi at 6:52–54: The mixer 5 mixes the output from the modulation format conversion unit 4, the output from the LNB 7, and the output from the antennas 3A and 3B. Oishi at 7:1–9:

Asserted Claims	Oishi
	The CS intermediate frequency signals which have undergone conversion of the modulation format and which have been frequency-shifted are fed from the terminal 14 via an RF through circuit and a distributor circuit of the BS tuner 12 to the CS tuner 13. The CS tuner 13 demodulates the CS intermediate frequency signals to obtain video signals and audio signals, for example, in the NTSC format. The output of the CS tuner 12 is fed to the other external video/audio input terminal Video(2) of the television receiver 11. Oishi at 7:51–59: The modulation format conversion unit 4 includes conversion circuits 4A, 4B, 4C, etc. The conversion circuits 4A, 4B, 4C, etc. receive CS intermediate frequency signals corresponding to the vertically polarized and horizontally polarized signals from each of the two satellites 8A and 8B, converts the modulation format of the signals, and frequency-shifts the signals into a vacant band for terrestrial television broadcasting. The conversion circuits 4A, 4B, 4C, etc. are configured identical to one another. Oishi at 7:60–65: Referring to FIG. 5, CS intermediate frequency signals output from the LNBs 9A and 9B of the parabola antennas 1A and 1B are fed to an input terminal 21. The signals input to the input terminal 21 are fed to each tuner circuit 22 of the modulation circuit 4A, 4B, 4C, etc. The tuner circuit 22 selects signals on a desired carrier wave. Oishi at 7:66–8:4: The output of the tuner circuit 22 is fed to a QPSK demodulation circuit 23. The QPSK demodulation circuit 23 demodulates the signals modulated by QPSK. The output of the QPSK circuit 23 is fed to an ECC (Error Correction Code) decoder 24. The output of the ECC decoder 24 is fed to an ECC encoder 25. Oishi at 8:21–27:

Asserted Claims	Oishi
	The tuner circuit 22, the QPSK demodulation circuit 23, the ECC decoder 24, the ECC encoder 25, the QAM modulation circuit 26, and the frequency conversion circuit 27 are controlled by a control circuit 30 via an interface 29. The control circuit is connected to an operation unit 31 which allows setting and to a display unit 32 for displaying the setting. Oishi at 8:28–42: As described above, in each of the conversion circuits 4A, 4B, 4C, etc. of the modulation format conversion unit 4, the QPSK demodulation circuit 23 and the QAM modulation circuit converts the modulation format of the signals corresponding to each of the carrier waves of the CS broadcasting signals from QPSK into 64-QAM, the ECC decoder 24 and the ECC encoder 25 reassigns error correction codes for the signals, and the frequency conversion circuit 27 frequency-shifts the signals into a vacant channel for terrestrial broadcasting. Thus, the CS signals from a single transponder having a bandwidth of, for example, 27 MHz, are accommodated in a narrower bandwidth, for example, 6 MHz, and the signals are then frequency-shifted into a vacant channel in the VHF band or the UHF band for terrestrial broadcasting. Oishi at 8:56–64: The tuner circuit 43 selects signals at a desired frequency from the CS signals shifted into a vacant channel in the VHF band or the UHF band. The output of the tuner circuit 43 is fed to a QAM demodulation circuit 44. The QAM demodulation circuit 44 demodulates the signals modulated by 64-QAM. The output of the QAM demodulation circuit 44 is fed to an ECC decoder 45. The ECC decoder 45 performs processing for error correction using Reed-Solomon codes. Oishi at 9:57–65: In accordance with the system, however, the CS intermediate frequency signals are frequency-shifted into a vacant channel in the VHF band or in the UHF band in the modulation format conversion unit 4 when the signals are transmitted to each household via the cable 10; thus, it is not feasible to set receive frequency directly from NIT

Asserted Claims	Oishi
	information. It may be possible, but very complex, to rewrite NIT information when the signals are frequency-shifted in the modulation format conversion unit 4. Oishi at [0093]: In accordance with the above-described embodiment, the modulation format of CS intermediate frequency signals is converted from QPSK into 64-QAM so that the signals are accommodated in a narrower bandwidth, and the signals are then frequency-shifted into a vacant band in the VHF mid band, the VHF super high band, or the UHF band. Accordingly, the CS broadcasting signals, even if serviced by two satellites, are allowed to be transmitted in a single cable together with BS broadcasting signals and terrestrial broadcasting signals. Oishi at [0094]: It is to be appreciated that although the modulation format is converted from QPSK into 64-QAM in the above-described embodiment, the present invention is not limited thereto, and the conversion may be any type from a modulating format compatible with signals from satellites to a modulating format which accommodates the signals in a narrower bandwidth which allows transmission in a single channel for terrestrial broadcasting. Oishi at [0095]: Furthermore, although the modulation format conversion unit 4 in the above-described embodiment performs conversion of modulation format and reassignment of error correction codes, the reassignment of error correction codes may be omitted. However, the reassignment of error correction code should preferably be incorporated so that the modulation format and the error correction coding format of the CS broadcasting signals transmitted via the cable 10 will be the same as those of the modulation format and the error correction coding format of digital CATV. This allows a settop box for digital CATV and the CS tuner to share a common chip, serving to reduce relevant cost.

Asserted Claims	Oishi
	To the extent Oishi does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Oishi alone or it would have been obvious to combine Oishi with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[d] a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal;	Oishi discloses, explicitly and/or inherently, a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal. *See, e.g.*: Oishi at 3:22–30: Accordingly, it is an object of the present invention to provide a television signal distribution apparatus, a receiver apparatus, and a television signal transmission system and method, which allows, without implementing large-scale works, terrestrial broadcasting signals in the VHF and UHF bands, the BS intermediate frequency signals, and CS intermediate frequency signals of a CS broadcasting service which employs two or more satellites to be multiplexed for transmission to each household via a single cable. Oishi at 3:31–53: To this end, the present invention provides a television signal transmission system including a television signal distributor apparatus which delivers signals received via a master antenna to each household via a cable; and at least one receiver apparatus provided in each household. The television signal distributor apparatus includes a modulation format converting unit for converting the modulation format of received CS broadcast signals to thereby accommodate the signals in a narrower bandwidth, and for frequency-shifting the signals accommodated in the narrower bandwidth into a vacant frequency band; and a mixing unit for mixing for transmission via the cable the frequency-shifted signals

Asserted Claims	Oishi
	accommodated in said narrower bandwidth with other type or types of received broadcast signals. The at least one receiver apparatus includes a receiving unit for receiving CS broadcast signals which have undergone conversion of modulation format so as to be accommodated in a narrower bandwidth and which have then been frequency-shifted into a vacant frequency band; a demodulating unit for demodulating the received signals in accordance with the modulation format after conversion; and a decoding unit for decoding the output from the demodulating unit to obtain video signals and audio signals. Oishi at 3:54–4:3: In accordance with the present invention, the modulation format of CS intermediate frequency signals is converted, for example, from QPSK to 64-QAM; thus, CS broadcasting signals from each transponder, having a bandwidth of, for example, 27 MHz, are accommodated in a bandwidth of, for example, 6 MHz, which is equivalent to a single channel for terrestrial broadcasting. The CS signals which have undergone conversion of the modulation format are frequency-shifted into a vacant channel in the VHF band or the UHF band. The frequency-shifted CS signals are multiplexed with BS intermediate frequency signals and terrestrial broadcasting signals for transmission to each household via a single cable. Accordingly, signals for a CS broadcasting service, even if provided via two or more satellites, can be transmitted to each household via a single cable together with signals for a BS broadcasting service and terrestrial broadcasting signals. Oishi at 6:35–42: The modulation format conversion unit 4 converts the modulation format of the CS intermediate signals, for example, from QPSK to 64-QAM, to accommodate the signals in a narrower bandwidth. The modulation format conversion unit 4 then frequency-shifts the signals accommodated in the narrower bandwidth into a vacant channel in the VHF band or in the UHF band. The output of the modulation format conversion unit 4 is fed to a mixer 5. Oishi at 6:43–48:

Asserted Claims	Oishi
	The BS parabola antenna 2 receives signals from a broadcasting satellite 6. The parabola antenna 2 is provided with an LNB 7. The LNB 7 converts signals in the 12-GHz band received by the parabola antenna 2 into intermediate frequency signals in the 1-GHz band. The output of the LNB 7 is fed to the mixer 5. Oishi at 6:49–51: The antennas 3A and 3B receive terrestrial broadcasting signals in the VHF and UHF bands. The outputs of the antennas 3A and 3B are fed to the mixer 5. Oishi at 6:52–54: The mixer 5 mixes the output from the modulation format conversion unit 4, the output from the LNB 7, and the output from the antennas 3A and 3B. Oishi at 6:55–56: The output of the mixer 5 is fed through a cable 10 and via a distributor to a terminal 14 in each household. Oishi at 7:13–23: As described above, in the television signal transmission system shown in FIG. 4, the modulation format conversion unit 4 converts the modulation format of the CS intermediate frequency signals so as to accommodate the signals in a narrower bandwidth, and frequency-shifts the signals into a vacant band in the VHF band or in the UHF band. Then, the output of the modulation format conversion unit 4 is multiplexed in the mixer 5 with the BS intermediate frequency signals and terrestrial broadcasting signals in the VHF and UHF bands, so that the mixed signals are transmitted to each household via the cable 10. Oishi at 8:43–45:

Asserted Claims	Oishi
	The output of each of the conversion circuits 4A, 4B, 4C, etc. are fed to the mixer 33. The output of the mixer 33 is fed to an output terminal 34. 10. The signal distribution system of claim 9 wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output.	Oishi discloses, explicitly and/or inherently, wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output. *See* claim 9, *supra*. *See, e.g.*: Oishi at 2:12–32:

Asserted Claims	Oishi
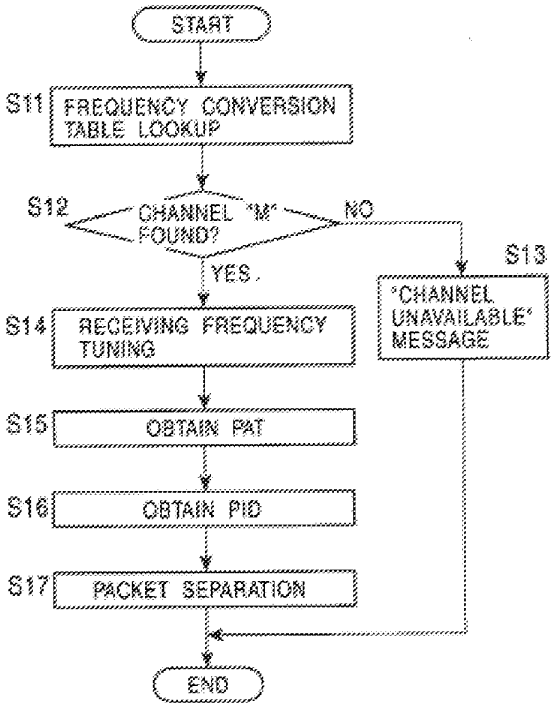
	More specifically, when BS intermediate frequency signals and the VHF-band and UHF-band terrestrial broadcasting signals are mixed for transmission via the same cable in the conventional television signal transmission systems, the frequency allocation of the mixed signals is as shown in FIG. 2. Referring to FIG. 2, the frequency allocation includes the VHF low band A 11, the VHF mid band A12, the VHF high band A13, the VHF super high band A14, the UHF band A15, and the frequency band A16 for BS intermediate frequency signals. When CS intermediate frequency signals are also mixed with the BS intermediate frequency signals and the VHF-band and UHF-band terrestrial broadcasting signals for transmission via the same cable, frequency bands A17 and A18 above the frequency band A16 for BS intermediate frequency signals are allocated respectively for vertically polarized signals and horizontally polarized signals of the CS intermediate frequency signals. The vertically polarized signals and the horizontally polarized signals of the CS intermediate frequency signals in the 1-GHz band B11 and B12 are frequency-shifted into the frequency bands A17 and A18. Oishi at 2:33–43: As described above, by frequency-shifting CS intermediate frequency signals so that the CS intermediate frequency signals are allocated in the frequency bands A 17 and A18 above the frequency band A16 for BS intermediate frequency signals, the frequency band A16 for BS intermediate frequency signals and the frequency bands A17 and A18 for CS intermediate frequency signals do not overlap, allowing the VHF-band and UHF-band terrestrial broadcasting signals, the BS intermediate frequency signals, and the CS intermediate frequency signals to be transmitted via a single cable. Oishi at 4:57–5:9: FIG. 3 shows the frequency allocation of signals transmitted via a cable. Referring to FIG. 3, A 1 (90 MHz to 108 MHz) is the VHF low band, A2 (108 MHz to 170 MHz) is the VHF mid band, A3 (170 MHz to 222 MHz) is the VHF high band, A4 (222 MHz to 470 MHz) is the VHF super high band, A5 (470 MHz to 770 MHz) is the UHF band, and A6 (1035



Asserted Claims	Oishi
	MHz to 1335 MHz) is a band for intermediate frequency signals of BS broadcasting signals. Currently, the VHF low band A1 and the VHF high band A3 are used for VHF terrestrial television broadcasting, and the UHF band A5 is used for UHF terrestrial television broadcasting. The VHF mid band A2 and the VHF super high band A4 are allocated for CATV (Cable Television), and therefore, the bands are vacant where CATV service is not used. The BS broadcasting signals are broadcast on electromagnetic waves in the 12-GHz band. When received via a parabola antenna, the BS broadcasting signals are converted into intermediate frequency signals in the 1-GHz band in an LNB (Low Noise Block Down Converter) provided in association with the parabola antenna. Oishi at 9:34–42: The setting for the CS tuner 13 is made via an operation unit 62, and the setting is displayed in a display unit 63. The control circuit 61 is provided with a frequency conversion table 64. The frequency conversion table 63 shows the correspondence between the frequency information of the satellite system shown in NIT (Network Information Table) and the frequency information of the transmission system of the signals transmitted via the cable 10. The frequency conversion table 64 is referenced when the receiving frequency is set in the tuner circuit 43. Oishi at 9:48–56: An ordinary CS broadcast receiver obtains NIT including information regarding carrier frequency characteristics, and based thereon, set the receive frequency to a desired channel. Then, reference is made to PAT (Program Association Table) packet. PAT includes information regarding channels on the carrier waves, and PID for PMT (Program Map Table) representing the contents for each of the channels. Based on the PAT information, video packets and audio packets for a desired channel on the carrier waves are separated, so that a desired program is received. Oishi at 9:57–65:

Asserted Claims	Oishi
	In accordance with the system, however, the CS intermediate frequency signals are frequency-shifted into a vacant channel in the VHF band or in the UHF band in the modulation format conversion unit 4 when the signals are transmitted to each household via the cable 10; thus, it is not feasible to set receive frequency directly from NIT information. It may be possible, but very complex, to rewrite NIT information when the signals are frequency-shifted in the modulation format conversion unit 4. Oishi at 9:66–10:3: Accordingly, in this embodiment, a frequency conversion table 54 is provided. The frequency conversion table stores the correspondence between frequency information for the satellite system obtained from the NIT and frequency information for the signal transmitted via the cable 10. Oishi at 10:4–10: In order to receive a desired program, NIT information must be obtained. NIT information is not frequently updated, and is provided once a day and stored in a storage medium within the receiver apparatus. FIG. 7 shows the data structure of NIT. NIT includes satellite delivery descriptor which describes frequency information and transmission parameters required to receive the signals. Oishi at 10:11–15: FIG. 8 shows the data structure of the satellite delivery descriptor. Information regarding programs for each channel is described in service list descriptor included in NIT. The data structure of the service list descriptor is shown in FIG. 9. Oishi at 10:16–23: In receive operation, first, information regarding the channel, i.e., frequency band, including a desired program is obtained from the service list descriptor and the satellite delivery descriptor included in NIT. Then, a frequency of the cable transmission system

Asserted Claims	Oishi
	corresponding to the obtained frequency is read from the frequency conversion table 64. The receive frequency of the tuner circuit 43 is set in accordance with the frequency read from the frequency conversion table 64. Oishi at 10:24–27: Then, reference is made to PAT packets, and based on PAT information, video packets and audio packets with PID corresponding to a desired channel are separated, so that a desired program is received. Oishi at 10:28–34: The frequency conversion table 64, which shows the correspondence between the frequency information of the satellite system described in NIT included in data transmitted from a satellite, and actual frequency information of the signals transmitted via the cable 10, is created when the system is initially powered on after the system is configured, in a processing as shown in FIG. 10. Oishi at 10:34–42: FIG. 10 is a flowchart showing an example of processing for creating the frequency conversion table 64 which shows the correspondence between the frequency information described in NIT of the satellite system and the frequency information of the cable transmission system. Referring to FIG. 10, in step S1, a desired channel is specified, for example, via a menu displayed on the screen, so that corresponding QAM signals are received and NIT information is obtained. Oishi at 10:43–58: In a television signal transmission system, once the frequency information of the cable transmission system is set, the information need not be frequently updated. In addition, channel information in the initial setting can be notified to the viewers by, for example, those in charge of management of the relevant facility. Thus, in step S 2, the frequency

Asserted Claims	Oishi
	information of the cable transmission system is input via, for example, initial setting menu displayed on the screen. Accordingly, the frequency conversion table 64, which shows the correspondence between the frequency information of the satellite system and the frequency information of the cable transmission system, is created and stored in memory in step S3. Because the channels for retransmission of the CS signals are fixed, i.e., the bands A2 and A4 in FIG. 3, the setting of frequency information can be made in accordance with the setting of the modulation format conversion unit 4 prior to shipping of receiver apparatuses. Oishi at 10:61–65: Referring to FIG. 11, first, reference is made to the frequency conversion table 64 in step S11. In step S12, it is determined whether the channel exists. If the "M" channel is not found, a "channel unavailable" message is displayed in step S13 to exit processing. Oishi at 10:66–11:3: If the channel "M" is found in step S 12, the frequency of the cable transmission system corresponding to the channel "M" is obtained from the frequency conversion table 64, and the receive frequency of the tuner circuit 43 is set thereto in step S14. Oishi at Fig. 10:

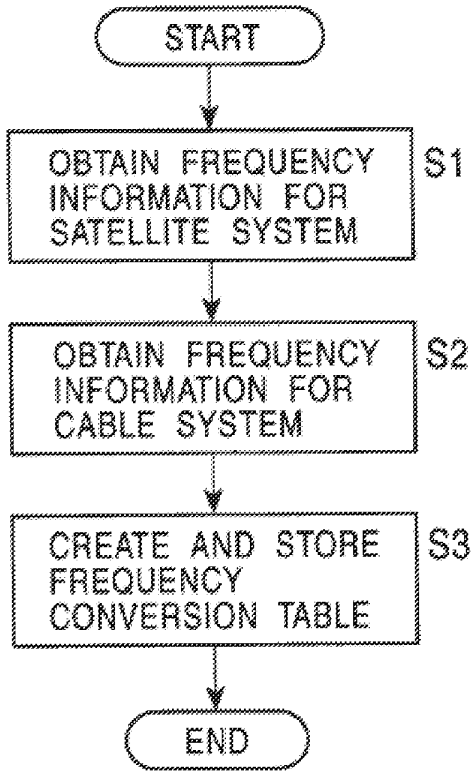
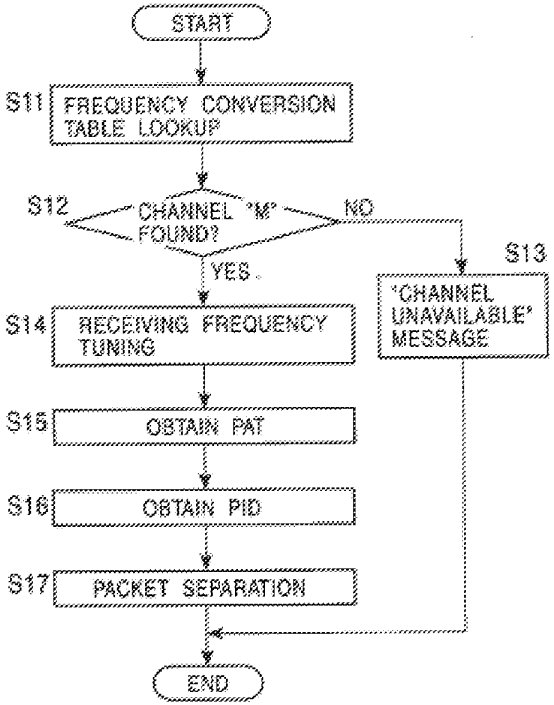
	FIG. 10  Oishi at Fig. 11:

Asserted Claims	Oishi
	FIG. 11  To the extent Oishi does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Oishi alone or it would have been obvious to combine Oishi with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Asserted Claims	Oishi
11. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network.	Oishi discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network. *See* claim 10, *supra*. *See, e.g.*: Oishi at 2:12–32: More specifically, when BS intermediate frequency signals and the VHF-band and UHF-band terrestrial broadcasting signals are mixed for transmission via the same cable in the conventional television signal transmission systems, the frequency allocation of the mixed signals is as shown in FIG. 2. Referring to FIG. 2, the frequency allocation includes the VHF low band A 11, the VHF mid band A12, the VHF high band A13, the VHF super high band A14, the UHF band A15, and the frequency band A16 for BS intermediate frequency signals. When CS intermediate frequency signals are also mixed with the BS intermediate frequency signals and the VHF-band and UHF-band terrestrial broadcasting signals for transmission via the same cable, frequency bands A17 and A18 above the frequency band A16 for BS intermediate frequency signals are allocated respectively for vertically polarized signals and horizontally polarized signals of the CS intermediate frequency signals. The vertically polarized signals and the horizontally polarized signals of the CS intermediate frequency signals in the 1-GHz band B11 and B12 are frequency-shifted into the frequency bands A17 and A18. Oishi at 2:33–43: As described above, by frequency-shifting CS intermediate frequency signals so that the CS intermediate frequency signals are allocated in the frequency bands A 17 and A18



Asserted Claims	Oishi
	above the frequency band A16 for BS intermediate frequency signals, the frequency band A16 for BS intermediate frequency signals and the frequency bands A17 and A18 for CS intermediate frequency signals do not overlap, allowing the VHF-band and UHF-band terrestrial broadcasting signals, the BS intermediate frequency signals, and the CS intermediate frequency signals to be transmitted via a single cable. Oishi at 4:57–5:9: FIG. 3 shows the frequency allocation of signals transmitted via a cable. Referring to FIG. 3, A 1 (90 MHz to 108 MHz) is the VHF low band, A2 (108 MHz to 170 MHz) is the VHF mid band, A3 (170 MHz to 222 MHz) is the VHF high band, A4 (222 MHz to 470 MHz) is the VHF super high band, A5 (470 MHz to 770 MHz) is the UHF band, and A6 (1035 MHz to 1335 MHz) is a band for intermediate frequency signals of BS broadcasting signals. Currently, the VHF low band A1 and the VHF high band A3 are used for VHF terrestrial television broadcasting, and the UHF band A5 is used for UHF terrestrial television broadcasting. The VHF mid band A2 and the VHF super high band A4 are allocated for CATV (Cable Television); and therefore, the bands are vacant where CATV service is not used. The BS broadcasting signals are broadcast on electromagnetic waves in the 12-GHz band. When received via a parabola antenna, the BS broadcasting signals are converted into intermediate frequency signals in the 1-GHz band in an LNB (Low Noise Block Down Converter) provided in association with the parabola antenna. Oishi at 9:34–42: The setting for the CS tuner 13 is made via an operation unit 62, and the setting is displayed in a display unit 63. The control circuit 61 is provided with a frequency conversion table 64. The frequency conversion table 63 shows the correspondence between the frequency information of the satellite system shown in NIT (Network Information Table) and the frequency information of the transmission system of the signals transmitted via the cable 10. The frequency conversion table 64 is referenced when the receiving frequency is set in the tuner circuit 43.



Asserted Claims	Oishi
	Oishi at 9:48–56: An ordinary CS broadcast receiver obtains NIT including information regarding carrier frequency characteristics, and based thereon, set the receive frequency to a desired channel. Then, reference is made to PAT (Program Association Table) packet. PAT includes information regarding channels on the carrier waves, and PID for PMT (Program Map Table) representing the contents for each of the channels. Based on the PAT information, video packets and audio packets for a desired channel on the carrier waves are separated, so that a desired program is received. Oishi at 9:57–65: In accordance with the system, however, the CS intermediate frequency signals are frequency-shifted into a vacant channel in the VHF band or in the UHF band in the modulation format conversion unit 4 when the signals are transmitted to each household via the cable 10; thus, it is not feasible to set receive frequency directly from NIT information. It may be possible, but very complex, to rewrite NIT information when the signals are frequency-shifted in the modulation format conversion unit 4. Oishi at 9:66–10:3: Accordingly, in this embodiment, a frequency conversion table 54 is provided. The frequency conversion table stores the correspondence between frequency information for the satellite system obtained from the NIT and frequency information for the signal transmitted via the cable 10. Oishi at 10:4–10: In order to receive a desired program, NIT information must be obtained. NIT information is not frequently updated, and is provided once a day and stored in a storage medium within the receiver apparatus. FIG. 7 shows the data structure of NIT. NIT includes

Asserted Claims	Oishi
	satellite delivery descriptor which describes frequency information and transmission parameters required to receive the signals. Oishi at 10:11–15: FIG. 8 shows the data structure of the satellite delivery descriptor. Information regarding programs for each channel is described in service list descriptor included in NIT. The data structure of the service list descriptor is shown in FIG. 9. Oishi at 10:16–23: In receive operation, first, information regarding the channel, i.e., frequency band, including a desired program is obtained from the service list descriptor and the satellite delivery descriptor included in NIT. Then, a frequency of the cable transmission system corresponding to the obtained frequency is read from the frequency conversion table 64. The receive frequency of the tuner circuit 43 is set in accordance with the frequency read from the frequency conversion table 64. Oishi at 10:24–27: Then, reference is made to PAT packets, and based on PAT information, video packets and audio packets with PID corresponding to a desired channel are separated, so that a desired program is received. Oishi at 10:28–34: The frequency conversion table 64, which shows the correspondence between the frequency information of the satellite system described in NIT included in data transmitted from a satellite, and actual frequency information of the signals transmitted via the cable 10, is created when the system is initially powered on after the system is configured, in a processing as shown in FIG. 10.

Asserted Claims	Oishi
	Oishi at 10:34–42: FIG. 10 is a flowchart showing an example of processing for creating the frequency conversion table 64 which shows the correspondence between the frequency information described in NIT of the satellite system and the frequency information of the cable transmission system. Referring to FIG. 10, in step S1, a desired channel is specified, for example, via a menu displayed on the screen, so that corresponding QAM signals are received and NIT information is obtained. Oishi at 10:43–58: In a television signal transmission system, once the frequency information of the cable transmission system is set, the information need not be frequently updated. In addition, channel information in the initial setting can be notified to the viewers by, for example, those in charge of management of the relevant facility. Thus, in step S 2, the frequency information of the cable transmission system is input via, for example, initial setting menu displayed on the screen. Accordingly, the frequency conversion table 64, which shows the correspondence between the frequency information of the satellite system and the frequency information of the cable transmission system, is created and stored in memory in step S3. Because the channels for retransmission of the CS signals are fixed, i.e., the bands A2 and A4 in FIG. 3, the setting of frequency information can be made in accordance with the setting of the modulation format conversion unit 4 prior to shipping of receiver apparatuses. Oishi at 10:61–65: Referring to FIG. 11, first, reference is made to the frequency conversion table 64 in step S11. In step S12, it is determined whether the channel exists. If the "M" channel is not found, a "channel unavailable" message is displayed in step S13 to exit processing. Oishi at 10:66–11:3:

Asserted Claims	Oishi
	If the channel "M" is found in step S 12, the frequency of the cable transmission system corresponding to the channel "M" is obtained from the frequency conversion table 64, and the receive frequency of the tuner circuit 43 is set thereto in step S14. Oishi at Fig. 10:

Asserted Claims	Oishi

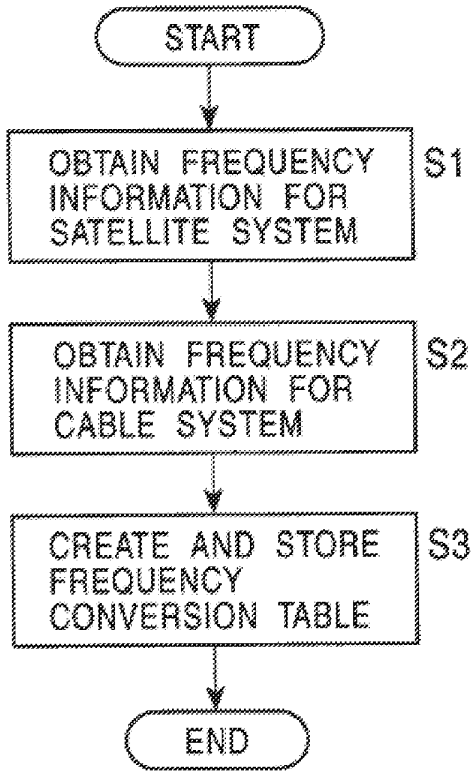
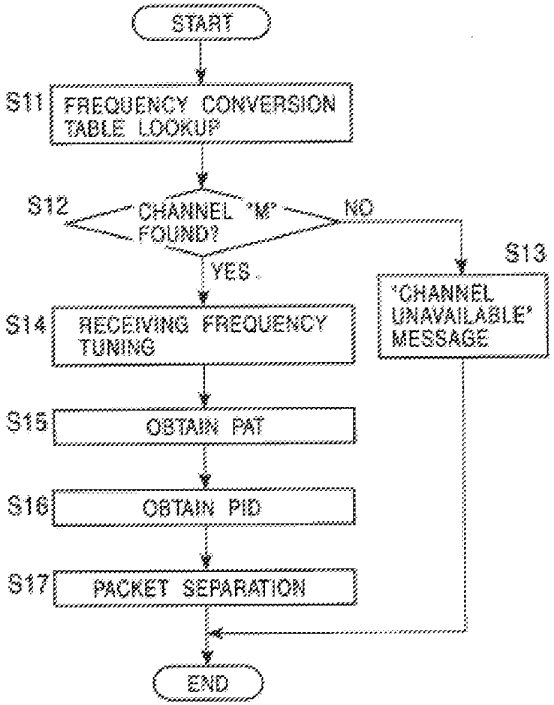
	FIG. 11  To the extent Oishi does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Oishi alone or it would have been obvious to combine Oishi with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Asserted Claims	Oishi
12. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network.	Oishi discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network. *See* claim 10, *supra*. *See, e.g.*: Oishi at 2:12–32: More specifically, when BS intermediate frequency signals and the VHF-band and UHF-band terrestrial broadcasting signals are mixed for transmission via the same cable in the conventional television signal transmission systems, the frequency allocation of the mixed signals is as shown in FIG. 2. Referring to FIG. 2, the frequency allocation includes the VHF low band A 11, the VHF mid band A12, the VHF high band A13, the VHF super high band A14, the UHF band A15, and the frequency band A16 for BS intermediate frequency signals. When CS intermediate frequency signals are also mixed with the BS intermediate frequency signals and the VHF-band and UHF-band terrestrial broadcasting signals for transmission via the same cable, frequency bands A17 and A18 above the frequency band A16 for BS intermediate frequency signals are allocated respectively for vertically polarized signals and horizontally polarized signals of the CS intermediate frequency signals. The vertically polarized signals and the horizontally polarized signals of the CS intermediate frequency signals in the 1-GHz band B11 and B12 are frequency-shifted into the frequency bands A17 and A18. Oishi at 2:33–43: As described above, by frequency-shifting CS intermediate frequency signals so that the CS intermediate frequency signals are allocated in the frequency bands A 17 and A18 above the frequency band A16 for BS intermediate frequency signals, the frequency band



Asserted Claims	Oishi
	A16 for BS intermediate frequency signals and the frequency bands A17 and A18 for CS intermediate frequency signals do not overlap, allowing the VHF-band and UHF-band terrestrial broadcasting signals, the BS intermediate frequency signals, and the CS intermediate frequency signals to be transmitted via a single cable. Oishi at 4:57–5:9: FIG. 3 shows the frequency allocation of signals transmitted via a cable. Referring to FIG. 3, A 1 (90 MHz to 108 MHz) is the VHF low band, A2 (108 MHz to 170 MHz) is the VHF mid band, A3 (170 MHz to 222 MHz) is the VHF high band, A4 (222 MHz to 470 MHz) is the VHF super high band, A5 (470 MHz to 770 MHz) is the UHF band, and A6 (1035 MHz to 1335 MHz) is a band for intermediate frequency signals of BS broadcasting signals. Currently, the VHF low band A1 and the VHF high band A3 are used for VHF terrestrial television broadcasting, and the UHF band A5 is used for UHF terrestrial television broadcasting. The VHF mid band A2 and the VHF super high band A4 are allocated for CATV (Cable Television); and therefore, the bands are vacant where CATV service is not used. The BS broadcasting signals are broadcast on electromagnetic waves in the 12-GHz band. When received via a parabola antenna, the BS broadcasting signals are converted into intermediate frequency signals in the 1-GHz band in an LNB (Low Noise Block Down Converter) provided in association with the parabola antenna. Oishi at 9:34–42: The setting for the CS tuner 13 is made via an operation unit 62, and the setting is displayed in a display unit 63. The control circuit 61 is provided with a frequency conversion table 64. The frequency conversion table 63 shows the correspondence between the frequency information of the satellite system shown in NIT (Network Information Table) and the frequency information of the transmission system of the signals transmitted via the cable 10. The frequency conversion table 64 is referenced when the receiving frequency is set in the tuner circuit 43.



Asserted Claims	Oishi
	Oishi at 9:48–56: An ordinary CS broadcast receiver obtains NIT including information regarding carrier frequency characteristics, and based thereon, set the receive frequency to a desired channel. Then, reference is made to PAT (Program Association Table) packet. PAT includes information regarding channels on the carrier waves, and PID for PMT (Program Map Table) representing the contents for each of the channels. Based on the PAT information, video packets and audio packets for a desired channel on the carrier waves are separated, so that a desired program is received. Oishi at 9:57–65: In accordance with the system, however, the CS intermediate frequency signals are frequency-shifted into a vacant channel in the VHF band or in the UHF band in the modulation format conversion unit 4 when the signals are transmitted to each household via the cable 10; thus, it is not feasible to set receive frequency directly from NIT information. It may be possible, but very complex, to rewrite NIT information when the signals are frequency-shifted in the modulation format conversion unit 4. Oishi at 9:66–10:3: Accordingly, in this embodiment, a frequency conversion table 54 is provided. The frequency conversion table stores the correspondence between frequency information for the satellite system obtained from the NIT and frequency information for the signal transmitted via the cable 10. Oishi at 10:4–10: In order to receive a desired program, NIT information must be obtained. NIT information is not frequently updated, and is provided once a day and stored in a storage medium within the receiver apparatus. FIG. 7 shows the data structure of NIT. NIT includes

Asserted Claims	Oishi
	satellite delivery descriptor which describes frequency information and transmission parameters required to receive the signals. Oishi at 10:11–15: FIG. 8 shows the data structure of the satellite delivery descriptor. Information regarding programs for each channel is described in service list descriptor included in NIT. The data structure of the service list descriptor is shown in FIG. 9. Oishi at 10:16–23: In receive operation, first, information regarding the channel, i.e., frequency band, including a desired program is obtained from the service list descriptor and the satellite delivery descriptor included in NIT. Then, a frequency of the cable transmission system corresponding to the obtained frequency is read from the frequency conversion table 64. The receive frequency of the tuner circuit 43 is set in accordance with the frequency read from the frequency conversion table 64. Oishi at 10:24–27: Then, reference is made to PAT packets, and based on PAT information, video packets and audio packets with PID corresponding to a desired channel are separated, so that a desired program is received. Oishi at 10:28–34: The frequency conversion table 64, which shows the correspondence between the frequency information of the satellite system described in NIT included in data transmitted from a satellite, and actual frequency information of the signals transmitted via the cable 10, is created when the system is initially powered on after the system is configured, in a processing as shown in FIG. 10.

Asserted Claims	Oishi
	Oishi at 10:34–42: FIG. 10 is a flowchart showing an example of processing for creating the frequency conversion table 64 which shows the correspondence between the frequency information described in NIT of the satellite system and the frequency information of the cable transmission system. Referring to FIG. 10, in step S1, a desired channel is specified, for example, via a menu displayed on the screen, so that corresponding QAM signals are received and NIT information is obtained. Oishi at 10:43–58: In a television signal transmission system, once the frequency information of the cable transmission system is set, the information need not be frequently updated. In addition, channel information in the initial setting can be notified to the viewers by, for example, those in charge of management of the relevant facility. Thus, in step S 2, the frequency information of the cable transmission system is input via, for example, initial setting menu displayed on the screen. Accordingly, the frequency conversion table 64, which shows the correspondence between the frequency information of the satellite system and the frequency information of the cable transmission system, is created and stored in memory in step S3. Because the channels for retransmission of the CS signals are fixed, i.e., the bands A2 and A4 in FIG. 3, the setting of frequency information can be made in accordance with the setting of the modulation format conversion unit 4 prior to shipping of receiver apparatuses. Oishi at 10:61–65: Referring to FIG. 11, first, reference is made to the frequency conversion table 64 in step S11. In step S12, it is determined whether the channel exists. If the "M" channel is not found, a "channel unavailable" message is displayed in step S13 to exit processing. Oishi at 10:66–11:3:

Asserted Claims	Oishi
	If the channel "M" is found in step S 12, the frequency of the cable transmission system corresponding to the channel "M" is obtained from the frequency conversion table 64, and the receive frequency of the tuner circuit 43 is set thereto in step S14. Oishi at Fig. 10:

Asserted Claims	Oishi
	FIG. 11  To the extent Oishi does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Oishi alone or it would have been obvious to combine Oishi with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Petruzzelli

U.S. Patent No. 5,959,592 ("Petruzzelli")[2] was filed on March 14, 1997 and issued on September 29, 1999. Petruzzelli therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(a), (b), and/or (e). For the reasons listed below, Petruzzelli invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Petruzzelli
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Petruzzelli discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*:

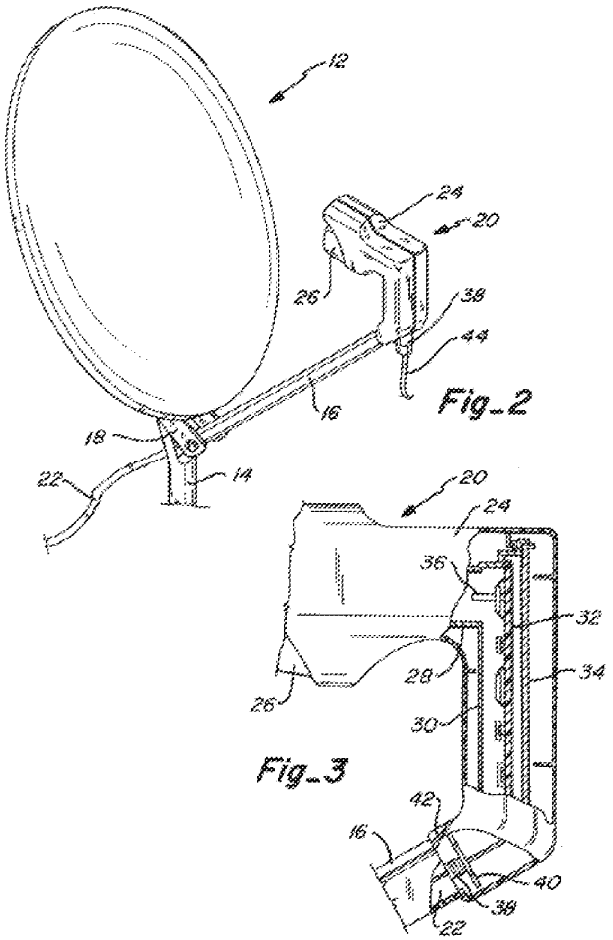
[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.

[2] Petruzzelli was incorporated by reference in the '715 patent. *See* '715 patent at 2:32–45.

Page 2097 of 4862

Asserted Claims	Petruzzelli
	Petruzzelli at Abstract: An arrangement is provided for combining the video and audio signals from a satellite antenna with other auxiliary input signals producing a frequency stacked band arrangement for transmission by a single cable to a satellite receiver or TV monitor located within a home or structure. Multiple TV input signals from the satellite antenna are processed and separated into intermediate frequency bands which are then combined in a diplexer with one or more auxiliary input frequency bands. The output of the diplexer is connected directly to the signal output terminal at the antenna. All components for performing this combining process are included within the sealed housing of the LNB provided at the satellite antenna. Improved band isolation and reduced noise and interference are produced by the novel arrangement. Petruzzelli at 1:1–17: This invention is directed to a combined LNB and diplexer mounted within a single microwave antenna feed housing. It is more specifically directed to the packaging of the electronic circuits of an LNB and a diplexer in the feed housing of a satellite receiving antenna so that the combined incoming RF signals from the satellite system and a terrestrial antenna can be fed simultaneously through an inexpensive coaxial cable to an appropriate TV receiver. Petruzzelli at 1:21–37: In the past, it has been common practice to provide a low noise amplifier as well as a block down converter within the antenna feed housing for a parabolic or concave microwave antenna. As is well known, radio frequency microwave energy strikes the surface of the parabolic antenna and is reflected to a focal point or locus where a feedhorn or feed is strategically positioned. The RF energy received is coupled to a wave guide which directs the radio frequency energy to the antenna probes. The received energy, whether in the "C-band" or "Ku-band" is amplified in a low noise amplifier to boost the strength of the signal and the signal is then converted usually by a factor of ten (10) through an oscillator and

Asserted Claims	Petruzzelli
	mixer stage comprising a down block converter to a considerably lower intermediate frequency. This frequency is more conducive to transmission to the receiver by means of a less expensive transmission wire or conduit, such as a simple coaxial cable. Petruzzelli at 1:38–62: When working with the satellite transmission of television and audio signals and because of government regulations, the satellite system microwave signals cannot include local broadcast television channels and FM and AM broadcasted audio channels because of the political requirements for protection of these local broadcast facilities. Thus, the satellite user also requires the addition of local broadcast signals to the antenna system in order to acquire a complete spectrum of video and audio programming. This is usually accomplished by the provision of a separate VHF/UHF radio frequency antenna or cable TV input for the reception of the local programing frequencies. Thus, the present systems require the inclusion of a number of separate lead-in conduits from various signal sources, such as a terrestrial TV or microwave antenna, a satellite broadcast antenna, a cable TV transmission input as well as other types of video and audio programing input signals. All of these require individual and separate lead-ins, such as parallel open wire, coaxial cables or twin lead cables which feed from the outside of a home or structure along with separate satellite cabling to a suitable receiver. The signals are then combined within the receiver and/or converter before they are fed into a television set or monitor. In this way, a multitude of cumbersome lead-in cables are required to provide all of the programming sources which are desired. Petruzzelli at 2:53–3:27: Along the left side of the figure is illustrated an antenna which, in essence, is a parabolic satellite antenna receiving downlinked microwave signals usually from a geostationary satellite. The frequencies of the received microwave signals are in the range of 12-13 Gigahertz. Because of the ability to receive polarized signals, the diagram illustrates the reception of signals in two separate frequency bands from the antenna 12. These are separate input signals and utilize the capability of the feedhorn or feed to separate the two



Asserted Claims	Petruzzelli
	polarized RF signals. Each signal is directly fed into a separate low noise amplifier and a separate block down converter 14, 16. The low noise amplifier amplifies the extremely low input signal received from the antenna and boosts it to a reasonable signal for processing. The block down converters include a mixer wherein the incoming RF signals are mixed with a local oscillator frequency signal whereby the incoming signals are combined and differentiated. The oscillator feeding the mixer contained within LNB 14 usually has a frequency of about 11.250 GHz. The oscillator feeding the mixer of the second LNB 16 is at a different frequency, such as about 10.650 GHz. The differential between the primary frequencies of the incoming signal and the oscillator signal provides the difference which is a considerably lower intermediate frequency. With the original incoming bandwidth approximately 500 MHz the output intermediate frequency from the first LNB 14 usually is in the range of 950-1450 MHz. The signal emitting from the second LNB 16 also has a bandwidth of approximately 500 MHz and lies in the frequency range of 1550-2050 MHz. In this way, there is two distinct band frequencies of 500 MHz each which are now at different base frequencies than the original incoming signals. These signals are then combined in a combiner included in the circuitry found within the feedhorn or feed 17 provided at the focal point of the parabolic satellite antenna. These incoming intermediate frequency bands contain all of the video and audio programming as well as the data provided in the TV satellite transmission. A coaxial cable 20 is fed from the combiner carrying the so called "stacked" intermediate frequency bands through the interface 21 of the support structure to the interior of the structure. Petruzzelli at 4:24–46: The Mutzig et al. patent (U.S. Pat. No. 5,276,904) provides a system for simultaneous reception of satellites and UHF/VHF frequencies. A microwave frequency head or LNBF includes a microwave frequency demodulation circuit which selects a chosen channel and demodulates it. The circuit is controlled by the satellite receiver. The unit further includes an amplitude remodulation circuit which converts the signal to signals in the 40-860 MHz band which is the same as the VHF/UHF channels received by the terrestrial TV receiving antennas. This satellite signal is combined through a multiplexer with the terrestrial received signals and the combined signal is then transmitted through a single cable to a

Asserted Claims	Petruzzelli
	converter and/or satellite receiver. The multiplexer is disclosed as being used in conjunction with a UHF/VHF antenna. There are several circuits which are also disclosed in this patent which allow the demodulation of the satellite signal and the direct transmission of this signal to the associated receiver positioned within the home or structure. None of these disclosures teach the inclusion of a diplexer within the LNBF housing for combining the UHF/VHF TV antenna signals with the incoming satellite signals for producing a stacked band of frequencies for transmission through the single lead-in cable. Petruzzelli at 4:47–58: The Theriault patent (U.S. Pat. No. 4,397,037) discloses the use of a diplexer for combining UHF input sources along with high frequency as well as low frequency TV frequency sources. Through use of a number of filters, these input signals are combined and delivered to a mixer section for processing the signals in a subsequent section of a broadcast TV signal processor. This patent merely teaches the use of various high pass and low pass filters for impedance matching and blending of signals into a common mixer for producing an intermediate frequency for later processing. It does not disclose the use of a diplexer or filters in the LNBF of a direct broadcast satellite antenna system. Petruzzelli at 4:59–68: The Oleson patent (U.S. Pat. No. 4,675,732) discloses the processing of an incoming satellite antenna signal in a low noise block down converter mounted at the antenna. The output of the LNB is delivered to a splitter where it is divided into various individual signals. The satellite incoming signals can be combined with local UHF/VHF TV signals in a matrix and selectively distributed to attached TV sets. There is no teaching in this patent of any combining of the satellite signals and the terrestrial antenna signals at the antenna receiving head. Petruzzelli at 5:1–15:

Asserted Claims	Petruzzelli
	The Green et al. patent (U.S. Pat. No. 5,073,930) discloses a television distribution system which includes a frequency agile satellite transponder down converter operating in the 950-1450 MHz frequency band along with an IF stage incorporating band pass filtering and a frequency agile up converter. This allows an antenna configuration with optimum selection of transponders from one or more satellites and with opposite polarization. The frequency block can then be distributed to multiple subscribers in various locations. This patent discloses multiple satellite signal inputs, but does not disclose the processing of the frequency bands into a frequency stacked band configuration nor the combining of the terrestrial television antenna output with the satellite signal output through the use of a diplexer mounted within the LNBF housing. Petruzzelli at 5:25–34: The Shingematsu et al. patent (European patent application No. 576012-A2) discloses a digital broadcast receiver comprising a satellite frequency converter and a cable frequency converter which are combined within a television receiver which includes a tuning circuit for selecting the input signal, whether analog or digital in the associated receiver. While this patent discloses the combining of various input signals, it does not teach or disclose the use of a diplexer or the location of the diplexer in the LNBF of a satellite receiving antenna. Petruzzelli at 5:38–45: The present invention is directed primarily to a satellite parabolic antenna which has an LNB mounted within a housing and located at the focal point of the antenna. A wave guide collects the incoming RF radio frequency energy and directs the signal to a plurality of individual antenna probes. For the sake of illustration, the probes as disclosed and discussed herein are arranged for reception of right and left hand polarized incoming RF signals. Petruzzelli at 5:62–6:21:

Asserted Claims	Petruzzelli
	In this way, the incoming RF signals are converted and separated into individual signal streams or bands having defined bandwidths which are independent and spaced from each other. It has been found that the first incoming band can have an intermediate frequency in the range of 950-1450 MHz while the second RF signal band is converted to a different frequency range, such as 1550-2050 MHz. The local oscillator frequencies are selected so that approximately one hundred MHz is provided as an isolation or separation band between these two intermediate frequency ranges. These signal bands are then combined and passed through a wide band intermediate frequency (IF) amplifier to boost the signal strength to an acceptable level. The signal then is passed through a high pass/low pass filter for separating out a DC operating voltage of approximately 13-18 volts which is fed to the LNB by the coaxial or other lead-in cable connecting the LNB with the appropriate satellite receiver. The receiver is adapted to provide the voltage for operation of the components within the LNB. This DC voltage is then processed through a regulated power supply which, in turn, is connected with the individual components and sections of the LNB. A diplexer which is essentially a high pass/low pass filter is provided between the output from the wide band amplifier to the output connector on the LNB for transferring the received RF video and audio signals to the connected satellite receiver. Petruzzelli at 6:22–36: This invention provides the unique feature of permitting the additional connection and introduction of other RF signal sources, such as the signals received by a VHF/UHF terrestrial TV antenna or external cable TV input directly into the antenna housing for the LNB. In this way, all of the signals converging at the exterior of the support structure for the antenna systems can be combined through the diplexer provided in the housing for combining all of these incoming signals into a stacked band arrangement for transmission through the attached coaxial cable or lead-in wire for transfer to the appropriate satellite receiver or TV monitor. The auxiliary incoming signals are connected through the high and low pass filters of the diplexer for matching the incoming impedance of the signal sources and combining these signals into a single signal stream.

Asserted Claims	Petruzzelli
	Petruzzelli 7:12–7:24: Turning now more specifically to the drawings, FIG. 2 shows a satellite type parabolic antenna 12 mounted on a support structure 14 and having an upwardly extending arm 16 mounted to bracket 18 and supporting an LNBF feed housing 20. A single output coaxial cable 22 is connected through the support arm 16 and LNBF feed housing for passage to the interior of the home or structure upon which the antenna is mounted. The cable 22 carries the output signals from the LNB housing and contains the satellite signals as well as any additionally attached auxiliary input signals. In this way, a single coaxial cable 22 carries all of the applicable RF signals for connection and operation to the satellite receiver and television set or monitor (not shown). Petruzzelli at 7:49–56: FIG. 4 is a block diagram showing the internal components mounted on the printed circuit board 32 and arranged to process the incoming signals received by the antenna 12 and guided through the wave guide 28 to the antenna probes 36. The satellite parabolic antenna 12 includes the feedhorn 20 precisely positioned at the focus of the antenna. The block diagrams which are shown in FIG. 4 are elements which are contained within the LNB feed housing 20. Petruzzelli at 9:65–10:10: It is important to understand that the novel results obtained in the present invention are produced by the inclusion of the diplexer within the LNB housing to minimize lead length between the LNB components and the diplexer for producing the combined stacked band frequency signals at the output 86 of the LNB. This is possible with the inclusion of the auxiliary inputs to the LNB housing for the combining of all of the desired frequency signals at the one output terminal. Thus, the components and connections are provided in a weather insulated environment to minimize contamination and prevent the introduction of noise and interference to the system.

Asserted Claims	Petruzzelli

Asserted Claims	Petruzzelli
	'715 patent at 2:32–45: U.S. Pat. No. 5,959,592 incorporated herein by reference, by Petruzzelli addresses combining both the left hand circular polarized (LHCP) and right hand circular polarized (RHCP) signals into one signal that is transmitted from the ODU. In the disclosed band stacking approach, the output of two low noise amplifiers (LNAs), each 500 MHz wide, are frequency translated to different IF frequencies and summed into a signal with a bandwidth of more than 1000 MHz. In one example disclosed, the different IF bands are 950 to 1450 MHz and 1550 to 2050 MHz. The problem with this approach is that the resulting bandwidth is very wide and becomes impractical when the number of LNB signals increases because each LNB output requires 500 MHz of bandwidth on the cable. To the extent Petruzzelli does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Petruzzelli alone or it would have been obvious to combine Petruzzelli with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[a] a gateway in communication with the ODU and at least one set top box (STB);	To the extent Petruzzelli does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Petruzzelli alone or it would have been obvious to combine Petruzzelli with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one	Petruzzelli discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*:

Asserted Claims	Petruzzelli
broadband LNB signal based on the transponder select information;	Petruzzelli at 2:40–49: In many direct broadcast satellite systems the transmission from the satellite is usually both right and left hand circular polarized. In this way, the actual bandwidth of the data being transmitted can be doubled to increase the capacity of the satellite. Thus, two separate bandwidth signals are transmitted simultaneously and received by the receiving antenna. In this way, two separate data streams are received by the common satellite parabolic antenna and these two signals each have a specific bandwidth and can be handled and processed separately. Petruzzelli at 2:53–3:27: Along the left side of the figure is illustrated an antenna which, in essence, is a parabolic satellite antenna receiving downlinked microwave signals usually from a geostationary satellite. The frequencies of the received microwave signals are in the range of 12-13 Gigahertz. Because of the ability to receive polarized signals, the diagram illustrates the reception of signals in two separate frequency bands from the antenna 12. These are separate input signals and utilize the capability of the feedhorn or feed to separate the two polarized RF signals. Each signal is directly fed into a separate low noise amplifier and a separate block down converter 14, 16. The low noise amplifier amplifies the extremely low input signal received from the antenna and boosts it to a reasonable signal for processing. The block down converters include a mixer wherein the incoming RF signals are mixed with a local oscillator frequency signal whereby the incoming signals are combined and differentiated. The oscillator feeding the mixer contained within LNB 14 usually has a frequency of about 11.250 GHz. The oscillator feeding the mixer of the second LNB 16 is at a different frequency, such as about 10.650 GHz. The differential between the primary frequencies of the incoming signal and the oscillator signal provides the difference which is a considerably lower intermediate frequency. With the original incoming bandwidth approximately 500 MHz the output intermediate frequency from the first LNB 14 usually is in the range of 950-1450 MHz. The signal emitting from the second LNB 16 also has a bandwidth of approximately 500 MHz and lies in the frequency range of 1550-2050 MHz.

Asserted Claims	Petruzzelli
	In this way, there is two distinct band frequencies of 500 MHz each which are now at different base frequencies than the original incoming signals. These signals are then combined in a combiner included in the circuitry found within the feedhorn or feed 17 provided at the focal point of the parabolic satellite antenna. These incoming intermediate frequency bands contain all of the video and audio programming as well as the data provided in the TV satellite transmission. A coaxial cable 20 is fed from the combiner carrying the so called "stacked" intermediate frequency bands through the interface 21 of the support structure to the interior of the structure. Petruzzelli at 4:24–46: The Mutzig et al. patent (U.S. Pat. No. 5,276,904) provides a system for simultaneous reception of satellites and UHF/VHF frequencies. A microwave frequency head or LNBF includes a microwave frequency demodulation circuit which selects a chosen channel and demodulates it. The circuit is controlled by the satellite receiver. The unit further includes an amplitude remodulation circuit which converts the signal to signals in the 40-860 MHz band which is the same as the VHF/UHF channels received by the terrestrial TV receiving antennas. This satellite signal is combined through a multiplexer with the terrestrial received signals and the combined signal is then transmitted through a single cable to a converter and/or satellite receiver. The multiplexer is disclosed as being used in conjunction with a UHF/VHF antenna. There are several circuits which are also disclosed in this patent which allow the demodulation of the satellite signal and the direct transmission of this signal to the associated receiver positioned within the home or structure. None of these disclosures teach the inclusion of a diplexer within the LNBF housing for combining the UHF/VHF TV antenna signals with the incoming satellite signals for producing a stacked band of frequencies for transmission through the single lead-in cable. Petruzzelli at 4:59–68: The Oleson patent (U.S. Pat. No. 4,675,732) discloses the processing of an incoming satellite antenna signal in a low noise block down converter mounted at the antenna. The

Asserted Claims	Petruzzelli
	output of the LNB is delivered to a splitter where it is divided into various individual signals. The satellite incoming signals can be combined with local UHF/VHF TV signals in a matrix and selectively distributed to attached TV sets. There is no teaching in this patent of any combining of the satellite signals and the terrestrial antenna signals at the antenna receiving head. Petruzzelli at 5:25–34: The Shingematsu et al. patent (European patent application No. 576012-A2) discloses a digital broadcast receiver comprising a satellite frequency converter and a cable frequency converter which are combined within a television receiver which includes a tuning circuit for selecting the input signal, whether analog or digital in the associated receiver. While this patent discloses the combining of various input signals, it does not teach or disclose the use of a diplexer or the location of the diplexer in the LNBF of a satellite receiving antenna. Petruzzelli at 5:38–45: The present invention is directed primarily to a satellite parabolic antenna which has an LNB mounted within a housing and located at the focal point of the antenna. A wave guide collects the incoming RF radio frequency energy and directs the signal to a plurality of individual antenna probes. For the sake of illustration, the probes as disclosed and discussed herein are arranged for reception of right and left hand polarized incoming RF signals. Petruzzelli at 5:46–61: For the purpose of this invention, it is also possible to include horizontal and vertical polarized or elliptical signals. As will be discussed later, these inputs can be replaced by other types of inputs, such as terrestrial microwave signals as well as other incoming signals for transfer to a suitable receiver or TV monitor. For the present, the discussion will be directed to the use of antenna probes to receive separate bandwidths of right and left hand polarized incoming video and audio signals. Each of the incoming signals follows a

Asserted Claims	Petruzzelli
	separate processing path whereby the signals are introduced into a low noise amplifier (LNA) and a band pass filter where they are then processed through separate block down converters. Each of the block down converters includes a mixer for combining a local oscillator frequency for producing an intermediate frequency signal band which is, in turn, again amplified and passed through a band pass filter. Petruzzelli at 5:62–6:21: In this way, the incoming RF signals are converted and separated into individual signal streams or bands having defined bandwidths which are independent and spaced from each other. It has been found that the first incoming band can have an intermediate frequency in the range of 950-1450 MHz while the second RF signal band is converted to a different frequency range, such as 1550-2050 MHz. The local oscillator frequencies are selected so that approximately one hundred MHz is provided as an isolation or separation band between these two intermediate frequency ranges. These signal bands are then combined and passed through a wide band intermediate frequency (IF) amplifier to boost the signal strength to an acceptable level. The signal then is passed through a high pass/low pass filter for separating out a DC operating voltage of approximately 13-18 volts which is fed to the LNB by the coaxial or other lead-in cable connecting the LNB with the appropriate satellite receiver. The receiver is adapted to provide the voltage for operation of the components within the LNB. This DC voltage is then processed through a regulated power supply which, in turn, is connected with the individual components and sections of the LNB. A diplexer which is essentially a high pass/low pass filter is provided between the output from the wide band amplifier to the output connector on the LNB for transferring the received RF video and audio signals to the connected satellite receiver. Petruzzelli at 7:63–8:39: Antenna probe 36 receives the incoming radio frequency (RF) video and audio signals encompassing a wide frequency band. In the preferred embodiment of this invention, this band is in the range of 12.2 to 12.7 GHz. E1 designates the data signal stream received through the antenna probe 36 which is connected to a low noise amplifier (LNA) contained

Asserted Claims	Petruzzelli
	within a special isolation housing 46 to minimize the introduction of noise and interference. It is understood that the incoming RF signal at this point is quite low and the low noise amplifier 44 is designed to amplify the signal to a much higher lever without the introduction of noise and interference to the signal. The signal is fed from the low noise amplifier through a first band pass filter 48 to a first mixer 50. The incoming RF data signal having a frequency in the band of 12.2 to 12.7 GHz is mixed with the frequency from a local oscillator having a predetermined frequency of 11.250 GHz. As is well known in frequency mixers of this type, a summation and difference of the combined frequencies are produced. As a result, a high frequency RF band and a lower frequency RF band are produced and amplified in the preamplifier 54. The increased signal is then passed through an intermediate frequency band pass filter designed to allow the passage of the lower intermediate frequencies in the band of 950-1450 MHz to pass through. All other frequencies, including the high intermediate frequency band, are blocked. In the same way, the second input frequency signal stream 36a having the same input frequency band is fed through a second separate low noise amplifier 60 and second band pass filter 62 to the second mixer 64. A second local oscillator 66 having a lower frequency than the frequency found in the first local oscillator is fed directly to the second mixer 64. The oscillator frequency in the second local oscillator 66 can be predetermined at 10.650 GHz in order to provide an intermediate frequency downstream of the second mixer in the bandwidth of 1550-2050 MHz. As can be seen, this second intermediate frequency band encompasses a bandwidth of 500 MHz and is above the intermediate frequency bandwidth of 950-1450 MHz provided in the first signal source. In this way, there is a guard band of approximately 100 MHz provided between the intermediate frequency bands of the first and second signal sources. This is what is called a "stacked band" arrangement. '715 patent at 2:32–45: U.S. Pat. No. 5,959,592 incorporated herein by reference, by Petruzzelli addresses combining both the left hand circular polarized (LHCP) and right hand circular polarized (RHCP) signals into one signal that is transmitted from the ODU. In the disclosed band stacking approach, the output of two low noise amplifiers (LNAs), each 500 MHz wide, are frequency translated to different IF frequencies and summed into a signal with a

Asserted Claims	Petruzzelli
	bandwidth of more than 1000 MHz. In one example disclosed, the different IF bands are 950 to 1450 MHz and 1550 to 2050 MHz. The problem with this approach is that the resulting bandwidth is very wide and becomes impractical when the number of LNB signals increases because each LNB output requires 500 MHz of bandwidth on the cable. To the extent Petruzzelli does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Petruzzelli alone or it would have been obvious to combine Petruzzelli with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Petruzzelli discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*: Petruzzelli at 1:63–2:14: Direct satellite broadcast systems generally use line-of-sight microwave and ultra high frequency (UHF) RF transmissions. In this part of the spectrum, radio frequency power losses associated with both feed lines and connectors are of major concern. This concern stems from the fact that at these high frequencies major loss of the signal can occur during the hard wire transmission of the signal through connectors and a coaxial cable from the antenna outside of the building to the receiver and TV located within the home or building. It is always a major concern to minimize these losses and to do it in an economical manner. As a result, it has been found that it is more economical and provides better results, if the frequency of the incoming received RF signal is down converted from the received microwave or ultra high frequency source to a lower intermediate frequency which can be transmitted more easily and efficiently over lower cost coaxial cable. As a

Page 2112 of 4862

Asserted Claims	Petruzzelli
	result, various methods have been attempted in the past to provide these more efficient transmitting arrangements. Petruzzelli at 2:53–3:27: Along the left side of the figure is illustrated an antenna which, in essence, is a parabolic satellite antenna receiving downlinked microwave signals usually from a geostationary satellite. The frequencies of the received microwave signals are in the range of 12-13 Gigahertz. Because of the ability to receive polarized signals, the diagram illustrates the reception of signals in two separate frequency bands from the antenna 12. These are separate input signals and utilize the capability of the feedhorn or feed to separate the two polarized RF signals. Each signal is directly fed into a separate low noise amplifier and a separate block down converter 14, 16. The low noise amplifier amplifies the extremely low input signal received from the antenna and boosts it to a reasonable signal for processing. The block down converters include a mixer wherein the incoming RF signals are mixed with a local oscillator frequency signal whereby the incoming signals are combined and differentiated. The oscillator feeding the mixer contained within LNB 14 usually has a frequency of about 11.250 GHz. The oscillator feeding the mixer of the second LNB 16 is at a different frequency, such as about 10.650 GHz. The differential between the primary frequencies of the incoming signal and the oscillator signal provides the difference which is a considerably lower intermediate frequency. With the original incoming bandwidth approximately 500 MHz the output intermediate frequency from the first LNB 14 usually is in the range of 950-1450 MHz. The signal emitting from the second LNB 16 also has a bandwidth of approximately 500 MHz and lies in the frequency range of 1550-2050 MHz. In this way, there is two distinct band frequencies of 500 MHz each which are now at different base frequencies than the original incoming signals. These signals are then combined in a combiner included in the circuitry found within the feedhorn or feed 17 provided at the focal point of the parabolic satellite antenna. These incoming intermediate frequency bands contain all of the video and audio programming as well as the data provided in the TV satellite transmission. A coaxial cable 20 is fed from the combiner

Asserted Claims	Petruzzelli
	carrying the so called "stacked" intermediate frequency bands through the interface 21 of the support structure to the interior of the structure. Petruzzelli at 3:42–52: The diagram at the lower portion of FIG. 1, illustrates the frequency bands of the RF signals which are transmitted through the interface 21 from the exterior of the structure to the appropriate location where the equipment is located within the structure. The VHF band is relatively narrow in comparison with the UHF bands being broader in bandwidth. The signals received from the satellite include the direct broadcast satellite signals which can have left hand and right hand circular polarization. As shown, the bandwidth of these signals are considerably broader than those of the VHF and UHF signals. Petruzzelli at 3:53–56: As illustrated herein, the prior art commonly provides a plurality of cables for conveying the signals from various RF sources to the appropriate converters or receivers within the structure where they can be satisfactorily used. Petruzzelli at 4:47–58: The Theriault patent (U.S. Pat. No. 4,397,037) discloses the use of a diplexer for combining UHF input sources along with high frequency as well as low frequency TV frequency sources. Through use of a number of filters, these input signals are combined and delivered to a mixer section for processing the signals in a subsequent section of a broadcast TV signal processor. This patent merely teaches the use of various high pass and low pass filters for impedance matching and blending of signals into a common mixer for producing an intermediate frequency for later processing. It does not disclose the use of a diplexer or filters in the LNBF of a direct broadcast satellite antenna system. Petruzzelli at 5:1–15:

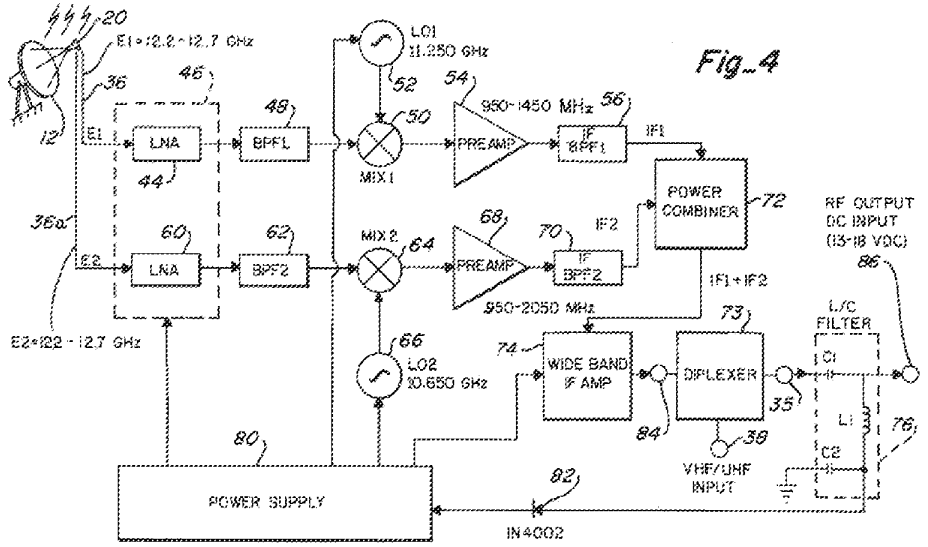
Asserted Claims	Petruzzelli
	The Green et al. patent (U.S. Pat. No. 5,073,930) discloses a television distribution system which includes a frequency agile satellite transponder down converter operating in the 950-1450 MHz frequency band along with an IF stage incorporating band pass filtering and a frequency agile up converter. This allows an antenna configuration with optimum selection of transponders from one or more satellites and with opposite polarization. The frequency block can then be distributed to multiple subscribers in various locations. This patent discloses multiple satellite signal inputs, but does not disclose the processing of the frequency bands into a frequency stacked band configuration nor the combining of the terrestrial television antenna output with the satellite signal output through the use of a diplexer mounted within the LNBF housing. Petruzzelli at 5:25–34: The Shingematsu et al. patent (European patent application No. 576012-A2) discloses a digital broadcast receiver comprising a satellite frequency converter and a cable frequency converter which are combined within a television receiver which includes a tuning circuit for selecting the input signal, whether analog or digital in the associated receiver. While this patent discloses the combining of various input signals, it does not teach or disclose the use of a diplexer or the location of the diplexer in the LNBF of a satellite receiving antenna. Petruzzelli at 5:46–61: For the purpose of this invention, it is also possible to include horizontal and vertical polarized or elliptical signals. As will be discussed later, these inputs can be replaced by other types of inputs, such as terrestrial microwave signals as well as other incoming signals for transfer to a suitable receiver or TV monitor. For the present, the discussion will be directed to the use of antenna probes to receive separate bandwidths of right and left hand polarized incoming video and audio signals. Each of the incoming signals follows a separate processing path whereby the signals are introduced into a low noise amplifier (LNA) and a band pass filter where they are then processed through separate block down converters. Each of the block down converters includes a mixer for combining a local

Asserted Claims	Petruzzelli
	oscillator frequency for producing an intermediate frequency signal band which is, in turn, again amplified and passed through a band pass filter. Petruzzelli at 5:62–6:21: In this way, the incoming RF signals are converted and separated into individual signal streams or bands having defined bandwidths which are independent and spaced from each other. It has been found that the first incoming band can have an intermediate frequency in the range of 950-1450 MHz while the second RF signal band is converted to a different frequency range, such as 1550-2050 MHz. The local oscillator frequencies are selected so that approximately one hundred MHz is provided as an isolation or separation band between these two intermediate frequency ranges. These signal bands are then combined and passed through a wide band intermediate frequency (IF) amplifier to boost the signal strength to an acceptable level. The signal then is passed through a high pass/low pass filter for separating out a DC operating voltage of approximately 13-18 volts which is fed to the LNB by the coaxial or other lead-in cable connecting the LNB with the appropriate satellite receiver. The receiver is adapted to provide the voltage for operation of the components within the LNB. This DC voltage is then processed through a regulated power supply which, in turn, is connected with the individual components and sections of the LNB. A diplexer which is essentially a high pass/low pass filter is provided between the output from the wide band amplifier to the output connector on the LNB for transferring the received RF video and audio signals to the connected satellite receiver. Petruzzelli at 6:37–50: By the unique combination of components within the LNB housing, fewer exposed connections and couplings are provided with all of the existing components protected from weather and contamination. In this way, lower cost, better efficiency and more reliable transmission of signals is possible. In addition, all of the intermediate frequency signals are transmitted through one relatively inexpensive cable or lead-in wire to the satellite receiver found within the home or structure. In addition, the intermediate frequency signals are stacked so that the individual frequency bands are separated and positioned one above the

Asserted Claims	Petruzzelli
	other so that they do not overlap. In this way, the bands do not interfere with each other and provide an extremely wide range of incoming frequency video and audio reception. Petruzzelli at 7:63–8:39: Antenna probe 36 receives the incoming radio frequency (RF) video and audio signals encompassing a wide frequency band. In the preferred embodiment of this invention, this band is in the range of 12.2 to 12.7 GHz. E1 designates the data signal stream received through the antenna probe 36 which is connected to a low noise amplifier (LNA) contained within a special isolation housing 46 to minimize the introduction of noise and interference. It is understood that the incoming RF signal at this point is quite low and the low noise amplifier 44 is designed to amplify the signal to a much higher lever without the introduction of noise and interference to the signal. The signal is fed from the low noise amplifier through a first band pass filter 48 to a first mixer 50. The incoming RF data signal having a frequency in the band of 12.2 to 12.7 GHz is mixed with the frequency from a local oscillator having a predetermined frequency of 11.250 GHz. As is well known in frequency mixers of this type, a summation and difference of the combined frequencies are produced. As a result, a high frequency RF band and a lower frequency RF band are produced and amplified in the preamplifier 54. The increased signal is then passed through an intermediate frequency band pass filter designed to allow the passage of the lower intermediate frequencies in the band of 950-1450 MHz to pass through. All other frequencies, including the high intermediate frequency band, are blocked. In the same way, the second input frequency signal stream 36a having the same input frequency band is fed through a second separate low noise amplifier 60 and second band pass filter 62 to the second mixer 64. A second local oscillator 66 having a lower frequency than the frequency found in the first local oscillator is fed directly to the second mixer 64. The oscillator frequency in the second local oscillator 66 can be predetermined at 10.650 GHz in order to provide an intermediate frequency downstream of the second mixer in the bandwidth of 1550-2050 MHz. As can be seen, this second intermediate frequency band encompasses a bandwidth of 500 MHz and is above the intermediate frequency bandwidth of 950-1450 MHz provided in the first signal source. In this way, there is a guard band of

Asserted Claims	Petruzzelli
	approximately 100 MHz provided between the intermediate frequency bands of the first and second signal sources. This is what is called a "stacked band" arrangement. '715 patent at 2:32–45: U.S. Pat. No. 5,959,592 incorporated herein by reference, by Petruzzelli addresses combining both the left hand circular polarized (LHCP) and right hand circular polarized (RHCP) signals into one signal that is transmitted from the ODU. In the disclosed band stacking approach, the output of two low noise amplifiers (LNAs), each 500 MHz wide, are frequency translated to different IF frequencies and summed into a signal with a bandwidth of more than 1000 MHz. In one example disclosed, the different IF bands are 950 to 1450 MHz and 1550 to 2050 MHz. The problem with this approach is that the resulting bandwidth is very wide and becomes impractical when the number of LNB signals increases because each LNB output requires 500 MHz of bandwidth on the cable. To the extent Petruzzelli does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Petruzzelli alone or it would have been obvious to combine Petruzzelli with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[d] a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal;	Petruzzelli discloses, explicitly and/or inherently, a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal. *See, e.g.*: Petruzzelli at 1:1–17: This invention is directed to a combined LNB and diplexer mounted within a single microwave antenna feed housing. It is more specifically directed to the packaging of the

Asserted Claims	Petruzzelli
	electronic circuits of an LNB and a diplexer in the feed housing of a satellite receiving antenna so that the combined incoming RF signals from the satellite system and a terrestrial antenna can be fed simultaneously through an inexpensive coaxial cable to an appropriate TV receiver. Petruzzelli at 3:57–62: The present invention eliminates the duplicity that is provided in the prior art and allows the conveyance of all input sources through one cable from the exterior of the structure to the interior. Thus, a much more inexpensive and efficient arrangement is provided which is easier and cheaper to install. Petruzzelli at 4:4–23: The Kang patent (U.S. Pat. No. 5,119,509) discloses a satellite receiving system having the capability of receiving both the C band as well as the Ku band, simultaneously. The signals are separately amplified through low noise amplifiers and are passed through a band pass filter to a single mixer. Dual switchable oscillators are provided in the mixing stage to establish an intermediate frequency, having a frequency band of 950-1450 MHz. The intermediate frequency signals are processed through a low pass filter and an intermediate frequency (IF) amplifier and a biasing stage for supplying DC bias voltage to the low noise amplifiers, local oscillators and the IF amplifiers. Low voltage operating power is received from the outlet cable source, such as a satellite receiver. A suitable filtering stage is provided for separating the DC voltage from the RF signal. The DC voltage is used in powering the LNBF components. Although this patent teaches two separate input signal sources, it does not disclose the use of a diplexer for combining exterior signal sources for combining and transmission through a single cable to the satellite receiver. Petruzzelli at 4:47–58: The Theriault patent (U.S. Pat. No. 4,397,037) discloses the use of a diplexer for combining UHF input sources along with high frequency as well as low frequency TV frequency sources. Through use of a number of filters, these input signals are combined



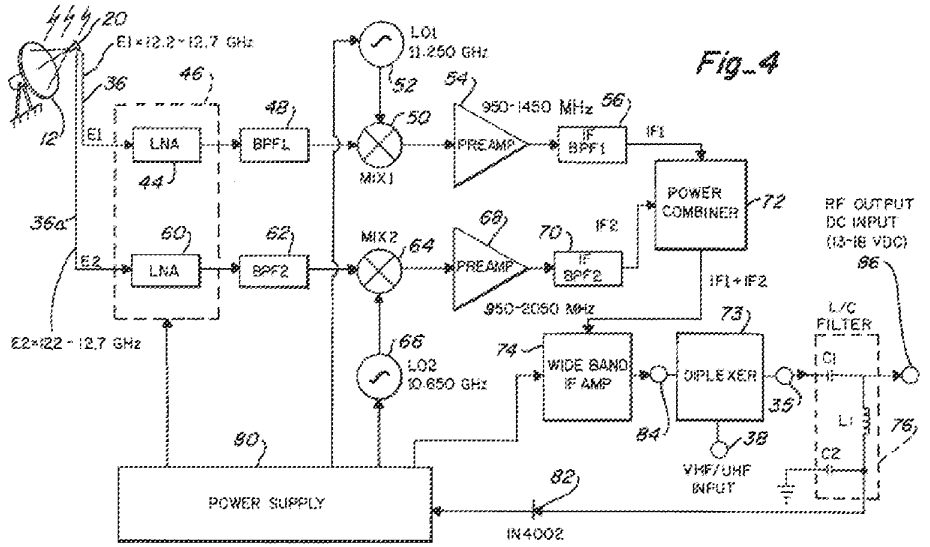
Asserted Claims	Petruzzelli
	and delivered to a mixer section for processing the signals in a subsequent section of a broadcast TV signal processor. This patent merely teaches the use of various high pass and low pass filters for impedance matching and blending of signals into a common mixer for producing an intermediate frequency for later processing. It does not disclose the use of a diplexer or filters in the LNBF of a direct broadcast satellite antenna system. Petruzzelli at 5:16–24: The Japanese patent to Yoshida (patent No. 5-129977) discloses a circuit which allows plural satellite broadcast receivers. A plurality of input antennas covering both satellite transmissions as well as UHF/VHF TV antenna signals are connected through various band pass filters to a mixer for connection to a tuner or a receiver. This patent does not in any way disclose the combination of a diplexer for combining UHF/VHF TV antenna signals with the output signals from a satellite antenna. Petruzzelli at 5:25–34: The Shingematsu et al. patent (European patent application No. 576012-A2) discloses a digital broadcast receiver comprising a satellite frequency converter and a cable frequency converter which are combined within a television receiver which includes a tuning circuit for selecting the input signal, whether analog or digital in the associated receiver. While this patent discloses the combining of various input signals, it does not teach or disclose the use of a diplexer or the location of the diplexer in the LNBF of a satellite receiving antenna. Petruzzelli at 5:46–61: For the purpose of this invention, it is also possible to include horizontal and vertical polarized or elliptical signals. As will be discussed later, these inputs can be replaced by other types of inputs, such as terrestrial microwave signals as well as other incoming signals for transfer to a suitable receiver or TV monitor. For the present, the discussion will be directed to the use of antenna probes to receive separate bandwidths of right and left hand polarized incoming video and audio signals. Each of the incoming signals follows a

Asserted Claims	Petruzzelli
	separate processing path whereby the signals are introduced into a low noise amplifier (LNA) and a band pass filter where they are then processed through separate block down converters. Each of the block down converters includes a mixer for combining a local oscillator frequency for producing an intermediate frequency signal band which is, in turn, again amplified and passed through a band pass filter. Petruzzelli at 5:62–6:21: In this way, the incoming RF signals are converted and separated into individual signal streams or bands having defined bandwidths which are independent and spaced from each other. It has been found that the first incoming band can have an intermediate frequency in the range of 950-1450 MHz while the second RF signal band is converted to a different frequency range, such as 1550-2050 MHz. The local oscillator frequencies are selected so that approximately one hundred MHz is provided as an isolation or separation band between these two intermediate frequency ranges. These signal bands are then combined and passed through a wide band intermediate frequency (IF) amplifier to boost the signal strength to an acceptable level. The signal then is passed through a high pass/low pass filter for separating out a DC operating voltage of approximately 13-18 volts which is fed to the LNB by the coaxial or other lead-in cable connecting the LNB with the appropriate satellite receiver. The receiver is adapted to provide the voltage for operation of the components within the LNB. This DC voltage is then processed through a regulated power supply which, in turn, is connected with the individual components and sections of the LNB. A diplexer which is essentially a high pass/low pass filter is provided between the output from the wide band amplifier to the output connector on the LNB for transferring the received RF video and audio signals to the connected satellite receiver. Petruzzelli at 6:22–36: This invention provides the unique feature of permitting the additional connection and introduction of other RF signal sources, such as the signals received by a VHF/UHF terrestrial TV antenna or external cable TV input directly into the antenna housing for the LNB. In this way, all of the signals converging at the exterior of the support structure for

Asserted Claims	Petruzzelli
	the antenna systems can be combined through the diplexer provided in the housing for combining all of these incoming signals into a stacked band arrangement for transmission through the attached coaxial cable or lead-in wire for transfer to the appropriate satellite receiver or TV monitor. The auxiliary incoming signals are connected through the high and low pass filters of the diplexer for matching the incoming impedance of the signal sources and combining these signals into a single signal stream. Petruzzelli at 7:63–8:39: Antenna probe 36 receives the incoming radio frequency (RF) video and audio signals encompassing a wide frequency band. In the preferred embodiment of this invention, this band is in the range of 12.2 to 12.7 GHz. E1 designates the data signal stream received through the antenna probe 36 which is connected to a low noise amplifier (LNA) contained within a special isolation housing 46 to minimize the introduction of noise and interference. It is understood that the incoming RF signal at this point is quite low and the low noise amplifier 44 is designed to amplify the signal to a much higher lever without the introduction of noise and interference to the signal. The signal is fed from the low noise amplifier through a first band pass filter 48 to a first mixer 50. The incoming RF data signal having a frequency in the band of 12.2 to 12.7 GHz is mixed with the frequency from a local oscillator having a predetermined frequency of 11.250 GHz. As is well known in frequency mixers of this type, a summation and difference of the combined frequencies are produced. As a result, a high frequency RF band and a lower frequency RF band are produced and amplified in the preamplifier 54. The increased signal is then passed through an intermediate frequency band pass filter designed to allow the passage of the lower intermediate frequencies in the band of 950-1450 MHz to pass through. All other frequencies, including the high intermediate frequency band, are blocked. In the same way, the second input frequency signal stream 36a having the same input frequency band is fed through a second separate low noise amplifier 60 and second band pass filter 62 to the second mixer 64. A second local oscillator 66 having a lower frequency than the frequency found in the first local oscillator is fed directly to the second mixer 64. The oscillator frequency in the second local oscillator 66 can be predetermined at 10.650 GHz in order to provide an intermediate frequency downstream of the second mixer in the bandwidth of

Asserted Claims	Petruzzelli
	1550-2050 MHz. As can be seen, this second intermediate frequency band encompasses a bandwidth of 500 MHz and is above the intermediate frequency bandwidth of 950-1450 MHz provided in the first signal source. In this way, there is a guard band of approximately 100 MHz provided between the intermediate frequency bands of the first and second signal sources. This is what is called a "stacked band" arrangement. Petruzzelli at 8:40–53: The combined resulting frequencies of the summation and difference of the frequencies introduced to the second mixer are passed directly through preamp 68 and the second intermediate frequency band pass filter 70. The second intermediate frequency band pass filer 70 filters out all of the extraneous frequencies except the desired intermediate frequencies in the 1550-2050 MHz frequency range. This band of frequencies is then introduced into the power combiner 72 along with the first source of incoming IF band frequencies. The first and second IF signal bands are combined in the combiner 72 to provide the "stacked band" arrangement mentioned above. The resulting signals are then fed through a wide band intermediate frequency amplifier 74. The output from the wide band amplifier 74 is then fed to a diplexer 78. Petruzzelli at 8:54–61: The diplexer 78 as shown in FIG. 5 provides the function of a high pass/low pass filter for the combining of the external auxiliary VHF/UHF input to the intermediate frequency band signals for passage through the RF output connector 86 to the connected satellite receiver. The diplexer provides a high pass filter through the output 84 from the wide band IF amplifier 74 containing the higher first and second intermediate frequency signal bands IF1, IF2. Petruzzelli at 8:62–9:13: The diplexer 78 is utilized in this arrangement since it provides the desired impedance matching at its respective inputs and output terminals. In addition, it permits signals from separate sources to be combined in a common circuit path without possible noise and

Asserted Claims	Petruzzelli
	distortion. In high pass filter 88, coupling capacitor C3 routes the combined UHF intermediate frequency signals through blocking capacitor C4 to internal circuit terminal 95. While, inductor L2 conducts relatively lower frequency signals to ground. Capacitors C3 and C4 are of relatively high capacitance to exhibit a relatively small impedance to signals at UHF frequencies. However, filter 88 shows a relatively high impedance at circuit terminal point 95 to lower frequency signals applied thereto from low pass filter 90. In high pass filter 88, capacitors C3 and C4 and inductor L2 serve as a simple 3 section filter and have values selected to cut-off at 950 MHz or slightly less. Thus, the high pass filter 88 has high impedance to the auxiliary lower frequency band which is being imported at the input terminal 38. Petruzzelli at 9:14–31: The low pass filter 90 of the diplexer 78 includes inductors L3, L4 in the line between the lower frequency band input terminal 38 and the circuit terminal point 95. A shunt capacitor C5 connected between the two inductors L3, L4 is connected directly to ground. Inductor L4 and shunt capacitors C5 and C6 serve as a simple 3 section filter and have a selective cut off value at or slightly above 812 MHz. In this way, low pass filter 90 presents a relatively high impedance to the higher frequency intermediate frequency bands so that these bands are directed through the internal terminal point 95 to the output 85 from the LNB. By the same token, the high pass filter 88 presents a relatively high impedance to the auxiliary lower input frequency band for VHF and UHF video and audio signals. The combined signals at output terminal 85 include essentially the three frequency bands shown in FIG. 5. These bands are stacked one above the other in series fashion and provide unique signal transmission to the applicable satellite receiver, tuner or TV monitor. Petruzzelli at 9:65–10:10: It is important to understand that the novel results obtained in the present invention are produced by the inclusion of the diplexer within the LNB housing to minimize lead length between the LNB components and the diplexer for producing the combined stacked band



Asserted Claims	Petruzzelli
	frequency signals at the output 86 of the LNB. This is possible with the inclusion of the auxiliary inputs to the LNB housing for the combining of all of the desired frequency signals at the one output terminal. Thus, the components and connections are provided in a weather insulated environment to minimize contamination and prevent the introduction of noise and interference to the system. Petruzzelli at Fig. 4:  '715 patent at 2:32–45: U.S. Pat. No. 5,959,592 incorporated herein by reference, by Petruzzelli addresses combining both the left hand circular polarized (LHCP) and right hand circular polarized (RHCP) signals into one signal that is transmitted from the ODU. In the disclosed band stacking approach, the output of two low noise amplifiers (LNAs), each 500 MHz wide,

Asserted Claims	Petruzzelli
	are frequency translated to different IF frequencies and summed into a signal with a bandwidth of more than 1000 MHz. In one example disclosed, the different IF bands are 950 to 1450 MHz and 1550 to 2050 MHz. The problem with this approach is that the resulting bandwidth is very wide and becomes impractical when the number of LNB signals increases because each LNB output requires 500 MHz of bandwidth on the cable. To the extent Petruzzelli does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Petruzzelli alone or it would have been obvious to combine Petruzzelli with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[e] wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs.	Petruzzelli discloses, explicitly and/or inherently, wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs. *See, e.g.*: Petruzzelli at 3:57–62: The present invention eliminates the duplicity that is provided in the prior art and allows the conveyance of all input sources through one cable from the exterior of the structure to the interior. Thus, a much more inexpensive and efficient arrangement is provided which is easier and cheaper to install. Petruzzelli at 4:4–23: The Kang patent (U.S. Pat. No. 5,119,509) discloses a satellite receiving system having the capability of receiving both the C band as well as the Ku band, simultaneously. The signals

Asserted Claims	Petruzzelli
	are separately amplified through low noise amplifiers and are passed through a band pass filter to a single mixer. Dual switchable oscillators are provided in the mixing stage to establish an intermediate frequency, having a frequency band of 950-1450 MHz. The intermediate frequency signals are processed through a low pass filter and an intermediate frequency (IF) amplifier and a biasing stage for supplying DC bias voltage to the low noise amplifiers, local oscillators and the IF amplifiers. Low voltage operating power is received from the outlet cable source, such as a satellite receiver. A suitable filtering stage is provided for separating the DC voltage from the RF signal. The DC voltage is used in powering the LNBF components. Although this patent teaches two separate input signal sources, it does not disclose the use of a diplexer for combining exterior signal sources for combining and transmission through a single cable to the satellite receiver. Petruzzelli at 4:24--46: The Mutzig et al. patent (U.S. Pat. No. 5,276,904) provides a system for simultaneous reception of satellites and UHF/VHF frequencies. A microwave frequency head or LNBF includes a microwave frequency demodulation circuit which selects a chosen channel and demodulates it. The circuit is controlled by the satellite receiver. The unit further includes an amplitude remodulation circuit which converts the signal to signals in the 40-860 MHz band which is the same as the VHF/UHF channels received by the terrestrial TV receiving antennas. This satellite signal is combined through a multiplexer with the terrestrial received signals and the combined signal is then transmitted through a single cable to a converter and/or satellite receiver. The multiplexer is disclosed as being used in conjunction with a UHF/VHF antenna. There are several circuits which are also disclosed in this patent which allow the demodulation of the satellite signal and the direct transmission of this signal to the associated receiver positioned within the home or structure. None of these disclosures teach the inclusion of a diplexer within the LNBF housing for combining the UHF/VHF TV antenna signals with the incoming satellite signals for producing a stacked band of frequencies for transmission through the single lead-in cable.

Asserted Claims	Petruzzelli
	Petruzzelli at 4:59–68: The Oleson patent (U.S. Pat. No. 4,675,732) discloses the processing of an incoming satellite antenna signal in a low noise block down converter mounted at the antenna. The output of the LNB is delivered to a splitter where it is divided into various individual signals. The satellite incoming signals can be combined with local UHF/VHF TV signals in a matrix and selectively distributed to attached TV sets. There is no teaching in this patent of any combining of the satellite signals and the terrestrial antenna signals at the antenna receiving head. Petruzzelli at 5:25–34: The Shingematsu et al. patent (European patent application No. 576012-A2) discloses a digital broadcast receiver comprising a satellite frequency converter and a cable frequency converter which are combined within a television receiver which includes a tuning circuit for selecting the input signal, whether analog or digital in the associated receiver. While this patent discloses the combining of various input signals, it does not teach or disclose the use of a diplexer or the location of the diplexer in the LNBF of a satellite receiving antenna. Petruzzelli at 8:54–61: The diplexer 78 as shown in FIG. 5 provides the function of a high pass/low pass filter for the combining of the external auxiliary VHF/UHF input to the intermediate frequency band signals for passage through the RF output connector 86 to the connected satellite receiver. The diplexer provides a high pass filter through the output 84 from the wide band IF amplifier 74 containing the higher first and second intermediate frequency signal bands IF1, IF2. Petruzzelli at 9:47–57: A common L/C filter 76 at the output of the diplexer 78 allows the IF signal to pass to the housing output connector 86. The coaxial cable 22 connected between the connector 86

Asserted Claims	Petruzzelli
	and the satellite receiver provided within the protection of the home or structure provides a source of unregulated DC voltage of approximately 13-18 volts DC. This voltage is applied through the RF output connector 86. This voltage passes directly to the L/C filter 76 where the DC voltage is blocked by capacitor C1 and passes through the L1/C2 portion of the filter 76 and through the diode 82 to the power supply 80. Petruzzelli at 9:65–10:10: It is important to understand that the novel results obtained in the present invention are produced by the inclusion of the diplexer within the LNB housing to minimize lead length between the LNB components and the diplexer for producing the combined stacked band frequency signals at the output 86 of the LNB. This is possible with the inclusion of the auxiliary inputs to the LNB housing for the combining of all of the desired frequency signals at the one output terminal. Thus, the components and connections are provided in a weather insulated environment to minimize contamination and prevent the introduction of noise and interference to the system. Petruzzelli at Fig. 4:

INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Williams '419

U.S. Patent No. 6,134,419 ("Williams '419")[2] was filed on January 20, 1998 and issued on October 17, 2000. Williams '419 therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(a) and/or (e). For the reasons listed below, Williams '419 invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Williams '419
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Williams '419 discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*:

[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.

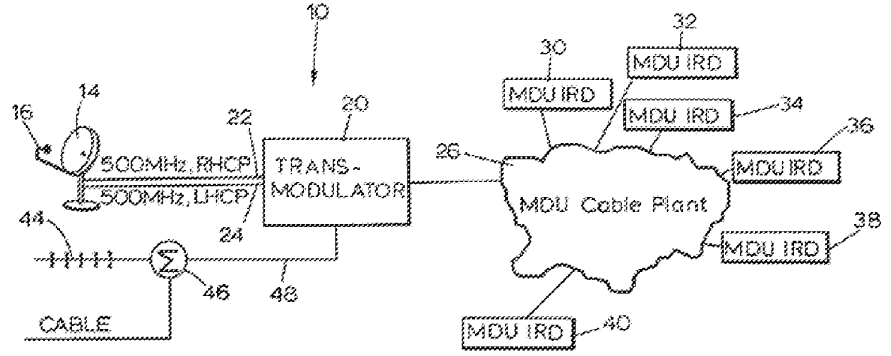
[2] Williams '419 was incorporated by reference in the '715 patent. *See* '715 patent at 2:7–24.

Page 2132 of 4862

Asserted Claims	Williams '419
	Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 1:10–15: The present invention relates generally to signal distribution systems and, more particularly, to audio/visual/data signal distribution systems that distribute satellite signals typically in conjunction with standard terrestrial and/or cable signals to a plurality of individual receivers within one or more multiple dwelling units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between

Asserted Claims	Williams '419
	about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 2:41–55: Furthermore, the receiving antennas or dishes associated with land-based or satellite-based wireless signal distribution systems are typically large and cumbersome. For example, C-band satellite dishes are generally in the range of four to five feet in diameter and, therefore, require a large amount of operating space. As a result, it can be difficult, if not practically impossible, to install a receiving antenna for each individual unit within a multiple dwelling unit (MDU), such as an apartment, condominium or townhome complex. Reception of a particular satellite signal is made even more difficult in MDUs when, as is generally the case, some of the individual dwelling units therein do not have any walls or outside exposure facing the direction in which the receiving antenna must be pointed, or these dwelling units are shadowed by surrounding buildings or other obstructions. Williams '419 at 3:9–27:

Asserted Claims	Williams '419
	One system proposed by the European Telecommunications Standards Institute (ETSI) in the area of Satellite Master Antenna Television (SMATV) receives a QPSK modulated satellite television signal (which may be combined with terrestrial TV signals) and remodulates this signal according to a 64 quadrature amplitude modulation (64-QAM) technique. The SMATV system then sends this remodulated signal out over cable to one or more adjacent buildings. Likewise, U.S. Pat. No. 5,173,775 discloses a system that remodulates data portions of a satellite television signal from one modulation scheme to another, such as from FM to AM, for retransmission to subscribers. However, these systems do not specifically demonstrate how to propagate remodulated satellite signals and existing cable or terrestrial signals on the same cable line or other transmission channel in an efficient manner or demonstrate how to remodulate and broadcast a large number of transponder signals associated with one or more satellites over the same cable line or other transmission channel to one or more adjacent buildings. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 3:48–65:



Asserted Claims	Williams '419
	According to another aspect of the present invention, a signal distribution system that distributes first and second signals over a communication channel to a plurality of individual receivers includes a main receiver and a second receiver disposed at a local site for receiving the first and second signals, respectively. A transmodulator coupled to the main receiver transmodulates the first signal from a first modulation scheme, such as a QPSK modulation scheme, to a second modulation scheme, such as a 128-QAM modulation scheme, to produce a transmodulated third signal. A signal combiner coupled to the second receiver and to the transmodulator combines the transmodulated third signal at a first set of carrier frequency bands and the second signal at a second set of carrier frequency bands to produce a combined signal. A transmitter then transmits the combined signal over a cable or a wireless network in a manner capable of being received at the plurality of individual receivers. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47:

Asserted Claims	Williams '419
	According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 4:48–54: Accordingly, apartment dwellers, for instance within a MDU system of this invention, can still use the dual mode IRD of the present invention if they move within a currently available SFH system, and conversely, single family home dwellers can still use the dual mode IRD of the present invention if they move within a MDU system of this invention. Williams '419 at 5:55–6:7: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM signals. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a

Asserted Claims	Williams '419
	transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '419 at 7:1–8: Each of the IRDs 30-40 receives the 32, QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates at least a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. Williams '419 at 13:13–37: Furthermore, while the signal distribution system 10 is described herein as using a 128-QAM modulator 102, any other type of QAM modulator, such as an 8-QAM, 32-QAM, or higher order QAM modulator can be used to encode the decoded satellite signal, with the choice being dependent on how much frequency spectrum is available on a particular cable system and on how noisy the cable network tends to be which, in turn, drives the level of error protection required. In general, the higher the order of QAM encoding, the less frequency spectrum will be necessary to transmit the desired number (e.g., 32) satellite transponder signals (or other signals) over a cable network. However, the higher the order of QAM modulation, the more the transmodulated signals will be susceptible to noise while being transmitted over a cable network. Likewise, different ones of the transmodulator channels of FIG. 3 may transmodulate the received PM signal, i.e., the tuned transponder signal, using different modulation schemes. For example, a first set of the transmodulator channels may remodulate PM signals using a 128-QAM modulation technique, while a second set of transmodulator channels may use a 32-QAM modulation technique, a 64-QAM modulation technique, and so on. The choice of the modulation technique for any particular transmodulator channel may depend on, for example, the data rate of the PM signal being received, as well as other factors. Williams '419 at 13:38–54:

Asserted Claims	Williams '419
	Furthermore, as noted above, modulation techniques besides QAM can be used when transmodulating the decoded satellite signal. Other such modulation techniques may include, for example, any high rate digital modulation techniques such as VSB (vestigial side band), including 8-VSB, 16-VSB etc., or QAM with trellis-coded modulation. Other modulation techniques which may be developed in the future could similarly be used without departing from the spirit and scope of the present invention. In general, the choice of a modulation technique will be driven by the reduction in bandwidth which must be accomplished by the modulation technique and by the noise susceptibility of the modulation technique. If a different modulation technique is used, however, it is understood that a different type of cable encoder will be necessary to properly transmodulate the desired transponder signals (or other received signals) for propagation over the cable network 26. Williams '419 at 13:55–14:3: Likewise, it is understood that signals other than QPSK modulated signals can be received at the main signal receiver 14 (or other receiver) and transmodulated for delivery over the cable network 26 using the concepts described herein. In this situation, the particulars of the transmodulator 20 will change based on the type of modulation, carrier frequencies and transmission formats associated with these different received signals. It is considered that the use of an 8-PSK (phase shift keying) modulation scheme for encoding the satellite signal and a 16-QAM or higher order QAM (32-QAM, 64-QAM etc.) scheme for encoding the cable signal may be one useful combination. It is also considered that the use of a 16-QAM scheme for encoding the satellite signal and a 32-QAM or higher order QAM scheme for encoding the cable signal may be another useful combination. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of

Asserted Claims	Williams '419
	the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 1:

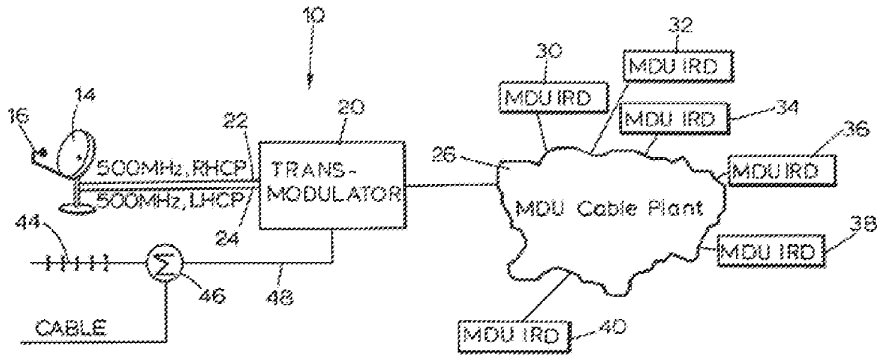
Asserted Claims	Williams '419
	 FIG. 1 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[a] a gateway in communication with the ODU and at least one set top box (STB);	Williams '419 discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual

Asserted Claims	Williams '419
	program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 3:48–65: According to another aspect of the present invention, a signal distribution system that distributes first and second signals over a communication channel to a plurality of individual receivers includes a main receiver and a second receiver disposed at a local site for receiving the first and second signals, respectively. A transmodulator coupled to the main receiver transmodulates the first signal from a first modulation scheme, such as a

Asserted Claims	Williams '419
	QPSK modulation scheme, to a second modulation scheme, such as a 128-QAM modulation scheme, to produce a transmodulated third signal. A signal combiner coupled to the second receiver and to the transmodulator combines the transmodulated third signal at a first set of carrier frequency bands and the second signal at a second set of carrier frequency bands to produce a combined signal. A transmitter then transmits the combined signal over a cable or a wireless network in a manner capable of being received at the plurality of individual receivers. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite

Asserted Claims	Williams '419
	signal distribution system and demodulating a selected one of the received modulated signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 5:55–6:7: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM signals. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the

Asserted Claims	Williams '419
	transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 6:28–51: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those which locally generate A-V channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '419 at 8:16–30: Referring now to FIG. 3, the transmodulator 20 includes bias tees 50 and 52 that receive the RHCP and LHCP QPSK-modulated satellite signals, respectively, at L-band from the LNB 16 (FIG. 1). The bias tee 50 provides a 13 volt DC signal to the LNB channel associated with the RHCP satellite signals, while the bias tee 52 provides a 17 volt DC signal to the LNB channel associated with the LHCP satellite signal. These DC voltages



Asserted Claims	Williams '419
	provide power to the respective LNB circuitry and select the desired polarization state in manners well known in the art. In this manner, standard LNBs configured to select polarization states based on the applied DC control voltage may be utilized. Other forms of LNBs permanently configured to operate in desired manners may alternatively be utilized, eliminating the need for the bias tees 50 and 52. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in

Asserted Claims	Williams '419
	the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 9:56–67: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. The control unit 72 may control, for example, tuning parameters, such as the output frequencies of the tuners 54 and may select the frequencies used by the upconverters 62 and 66 and/or

Asserted Claims	Williams '419
	the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 10:63–11:10: In the embodiment of FIG. 3, the control unit 72 preferably searches for continuous 24 MHz-wide unused frequency bands within which to place each of the eight groups of four, 6 MHz-wide signals developed by the summers 64. Alternatively, the control unit 72 could

Asserted Claims	Williams '419
	search for any smaller or larger continuous band of unused frequencies for use in transmitting any other desired groupings of the 32, 6 MHz-wide transmodulated signals. The control unit 72 may control the level shifter 70 to frequency-translate the terrestrial signals received at the frequency bands identified for use by the transmodulated signals in any conventional manner. Also, the control unit 72 may establish a communication channel with the IRDs 30-40 and signal the location, order, etc. of the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over this channel. Williams '419 at 13:1–12: While the transmodulator 20 is described herein as including a packetizer 58 which repacketizes 130 byte data packets produced by a standard DSS satellite decoder 56 into standard 188 byte data packets used by systems following the DVB transmission standard to enable the use of known DSS satellite decoders and known DVB cable encoders, the transmodulator 20 could, instead, include circuitry specifically designed to encode the 130 byte data packets produced by the satellite decoder 56 in a manner similar to the DVB cable encoder, i.e., by scrambling, R-S encoding, interleaving, etc. the 130 byte data packets to produce the 128-QAM modulated signals. Williams '419 at 13:13–37: Furthermore, while the signal distribution system 10 is described herein as using a 128-QAM modulator 102, any other type of QAM modulator, such as an 8-QAM, 32-QAM, or higher order QAM modulator can be used to encode the decoded satellite signal, with the choice being dependent on how much frequency spectrum is available on a particular cable system and on how noisy the cable network tends to be which, in turn, drives the level of error protection required. In general, the higher the order of QAM encoding, the less frequency spectrum will be necessary to transmit the desired number (e.g., 32) satellite transponder signals (or other signals) over a cable network. However, the higher the order of QAM modulation, the more the transmodulated signals will be susceptible to noise while being transmitted over a cable network. Likewise, different ones of the transmodulator channels of FIG. 3 may transmodulate the received PM signal, i.e., the

Asserted Claims	Williams '419
	tuned transponder signal, using different modulation schemes. For example, a first set of the transmodulator channels may remodulate PM signals using a 128-QAM modulation technique, while a second set of transmodulator channels may use a 32-QAM modulation technique, a 64-QAM modulation technique, and so on. The choice of the modulation technique for any particular transmodulator channel may depend on, for example, the data rate of the PM signal being received, as well as other factors. Williams '419 at 13:55–14:3: Likewise, it is understood that signals other than QPSK modulated signals can be received at the main signal receiver 14 (or other receiver) and transmodulated for delivery over the cable network 26 using the concepts described herein. In this situation, the particulars of the transmodulator 20 will change based on the type of modulation, carrier frequencies and transmission formats associated with these different received signals. It is considered that the use of an 8-PSK (phase shift keying) modulation scheme for encoding the satellite signal and a 16-QAM or higher order QAM (32-QAM, 64-QAM etc.) scheme for encoding the cable signal may be one useful combination. It is also considered that the use of a 16-QAM scheme for encoding the satellite signal and a 32-QAM or higher order QAM scheme for encoding the cable signal may be another useful combination. Williams '419 at 14:11–26: The IRD 30 may initially scan all the channels from, for example, low carrier frequencies to high carrier frequencies, to locate the frequency bands or channels used by the 32 transmodulated signals and then assign channel numbers to these located signals based on a predetermined ordering scheme used by the transmodulator 20. However, the transmodulator 20 may actively signal the channel locations, ordering, frequency assignments, etc. of the transmodulated satellite signals and/or terrestrial signals via a communication channel established over, for example, the cable network 26. Such a communication channel may comprise a low-speed channel that uses uncoded bits of the sync and error code bytes within the, for example, 188 byte data packets, and may be used

Asserted Claims	Williams '419
	to deliver any desired information to the IRD 30 over time, i.e., using a large number of the 188 byte data packets. Williams '419 at Fig. 1:  FIG. 1 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of	Williams '419 discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*:

Asserted Claims	Williams '419
transponder signals from at least one broadband LNB signal based on the transponder select information;	Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified

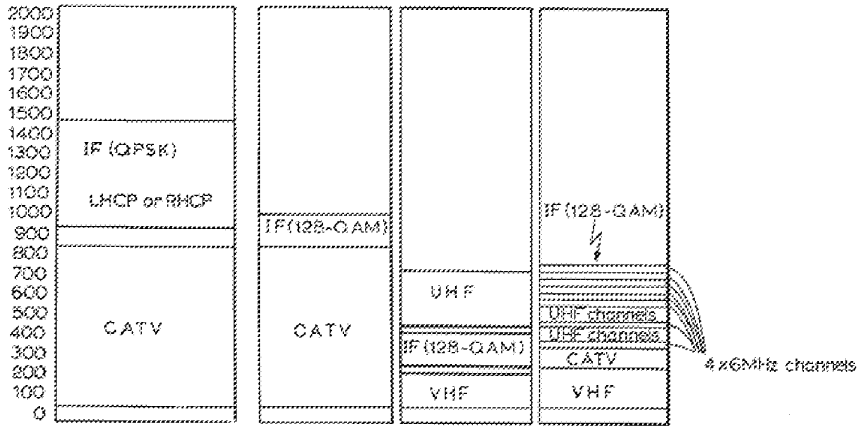
Asserted Claims	Williams '419
	channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes.

Asserted Claims	Williams '419
	Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 6:52–67: Preferably, the transmodulator 20 transmodulates the two 500 MHz-wide QPSK-modulated downlink signals into a 128-QAM-modulated signal having 32, 6 MHz-wide channels, wherein each of the 6 MHz-wide channels corresponds to one of the 32 original transponder signals. The transmodulator 20 may then place each of these 32, 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate the received satellite signals. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '419 at 7:1–8:

Asserted Claims	Williams '419
	Each of the IRDs 30-40 receives the 32, QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates at least a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:56–67: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. The control unit 72 may control, for example, tuning parameters, such as the output frequencies of the tuners 54 and may select the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are

Asserted Claims	Williams '419
	received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:28–33: After the control unit 72 identifies all of the empty or unused frequency bands, this information is preferably stored in non-volatile memory. Operator selection (e.g., by means of a keypad) may also be utilized to select or de-select frequency bands, either alone or in conjunction with an automated system. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Williams '419 discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*:

Asserted Claims	Williams '419
	Williams '419 at 1:29–43: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other



Asserted Claims	Williams '419
	transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the

Asserted Claims	Williams '419
	transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all

Asserted Claims	Williams '419
	of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same

Asserted Claims	Williams '419
	modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter

Asserted Claims	Williams '419
	66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte

Asserted Claims	Williams '419
	data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 2:  FIG. 2 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Asserted Claims	Williams '419
9[d] a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal;	Williams '419 discloses, explicitly and/or inherently, a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal. *See, e.g.:* Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is

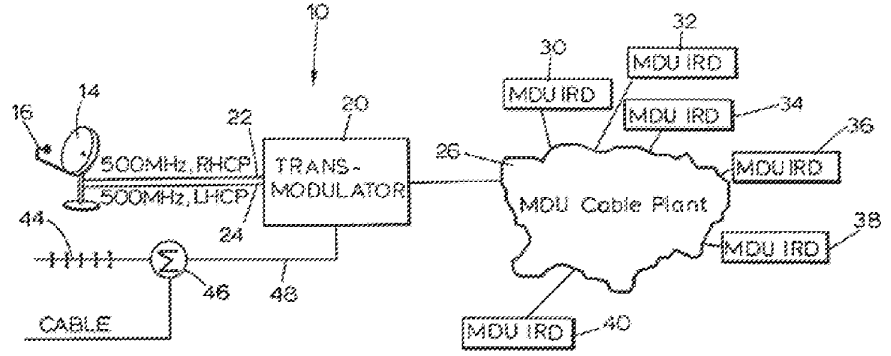
Asserted Claims	Williams '419
	smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated

Asserted Claims	Williams '419
	signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 4:48–54: Accordingly, apartment dwellers, for instance within a MDU system of this invention, can still use the dual mode IRD of the present invention if they move within a currently available SFH system, and conversely, single family home dwellers can still use the dual mode IRD of the present invention if they move within a MDU system of this invention. Williams '419 at 5:25–40: By the way of example only, the signal distribution system of the present invention is described herein as redistributing a broadband Ku-band satellite signal (comprising up to 32, QPSK-modulated transponder signals transmitted from one or more satellites at a carrier frequency band centered around approximately 12.45 GHz) to receiver units within an MDU. It is understood however, that the signal distribution system of the present invention can be used to redistribute any other type of satellite or land-based wireless signal. The term program multiplex (PM) signal is used herein to describe any single or multiplex of purely visual (such as video), purely audio, or purely data signals as well as a signal comprising any combination of audio, visual, data or other signals including, for example, television signals, digital data signals, etc. Williams '419 at 7:9–36: Referring now to FIG. 2, representative methods of combining the transmodulated transponder signals along with terrestrial signals on the cable network 26 are illustrated. The left-most column of FIG. 2 illustrates a previously known method of placing QPSK-modulated signals along with terrestrial signals on a cable network. According to this scheme, all existing terrestrial signals (including cable TV signals) are distributed at, for example, VHF and UHF carrier frequencies below 950 MHz while one of the 500 MHz-wide QPSK-modulated signals (associated with either the LHCP or the RHCP component

Asserted Claims	Williams '419
	of the satellite signal) is placed directly on the cable network at the unused band between about 950 MHz and 1450 MHz. A major problem with this configuration is that only the RHCP or the LHCP transponder signals can be placed on a standard cable network at any given time which, in turn, prevents IRDs within an MDU from decoding or receiving channels associated with the other of the LHCP or the RHCP transponder signals. While this problem can be overcome by running two cable lines throughout an MDU or by utilizing a high frequency cable plant capable of approximately 2 GHz or greater bandwidth, these solutions require additional equipment and expense and are not adaptable to most existing cable plants now in use. Furthermore, the signals provided at the 950 MHz to 1450 MHz band can be severely degraded by the cable plant due to the poor high frequency propagation properties of many existing cable plants, especially older cable plants. Williams '419 at 7:37–46: The three right-most columns of FIG. 2 illustrate methods of combining the 32, 6 MHz-wide, 128-QAM-modulated signals with existing terrestrial signals on the cable network 26. The second left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals in sequence at a band between about 806 MHz and 998 MHz directly above the common CATV channels. This configuration can be used with higher grade cable networks that propagate signals at up to 1000 MHz without significant degradation. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier

Asserted Claims	Williams '419
	frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[e] wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs.	Williams '419 discloses, explicitly and/or inherently, wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs. *See, e.g.*: Williams '419 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme to reduce the bandwidth of the broadband signal. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. A dual mode receiver is compatible with the MDU system and with a

Asserted Claims	Williams '419
	known digital satellite system commonly used in single family housing (SFH). An adapter enables a standard SFH receiver used in a digital satellite system to be compatible with the MDU system. Williams '419 at 1:10–15: The present invention relates generally to signal distribution systems and, more particularly, to audio/visual/data signal distribution systems that distribute satellite signals typically in conjunction with standard terrestrial and/or cable signals to a plurality of individual receivers within one or more multiple dwelling units. Williams '419 at 3:30–47: The present invention relates to a system and method for distributing a set of program multiplexed A-V signals and existing terrestrial signals to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates the broadband signal into a modulated signal having a bandwidth which is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. Williams '419 at 4:13–32: According to another aspect of the present invention, a signal distribution system distributes a composite signal modulated according to a first modulation scheme over a cable or a wireless network in a manner capable of being received by a plurality of individual receivers at a local site. The composite signal includes a plurality of program



Asserted Claims	Williams '419
	multiplex (PM) signals wherein each PM signal includes data related to a number of audio, video, and/or data signals. The signal distribution system includes a main receiver for receiving the composite signal and a plurality of transmodulator channels coupled to the main receiver, each of which transmodulates one of the plurality of PM signals from the first modulation scheme to a second modulation scheme to produce one of a plurality of transmodulated signals. A combiner combines the plurality of transmodulated signals at different carrier frequency bands to produce a combined signal and, thereafter, a transmitter transmits the combined signal over the cable or wireless network in a manner capable of being received by the plurality of individual receivers at the local site. Williams '419 at 4:33–47: According to a further aspect of the present invention, a single dual mode IRD unit can be used in an MDU system of this invention and also is compatible with satellite signal distribution systems currently used predominantly in a single family home (SFH). The single dual mode IRD receives the transmodulated signals and demodulates a selected one of the transmodulated signals in an MDU signal distribution system of this invention. The dual mode IRD also is capable of receiving modulated signals in a known SFH satellite signal distribution system and demodulating a selected one of the received modulated signals. In important embodiments, the transmodulated signals and the SFH signals utilize different modulation schemes, and the dual mode IRD is capable of selectively demodulating both such modulation schemes. Williams '419 at 4:48–54: Accordingly, apartment dwellers, for instance within a MDU system of this invention, can still use the dual mode IRD of the present invention if they move within a currently available SFH system, and conversely, single family home dwellers can still use the dual mode IRD of the present invention if they move within a MDU system of this invention. Williams '419 at 4:55–61:

Asserted Claims	Williams '419
	In a still further aspect of this invention, an MDU adapter enables a presently available IRD used within a current signal distribution system for SFHs (SFH IRD), to be compatible with a signal distribution system for MDUs of this invention. The MDU adapter demodulates a selected one of the received MDU network signals and modulates the selected signal in a manner compatible with the SFH IRD. Williams '419 at 5:55–6:7: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM signals. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '419 at 6:52–67: Preferably, the transmodulator 20 transmodulates the two 500 MHz-wide QPSK-modulated downlink signals into a 128-QAM-modulated signal having 32, 6 MHz-wide channels, wherein each of the 6 MHz-wide channels corresponds to one of the 32 original transponder signals. The transmodulator 20 may then place each of these 32, 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate the received satellite

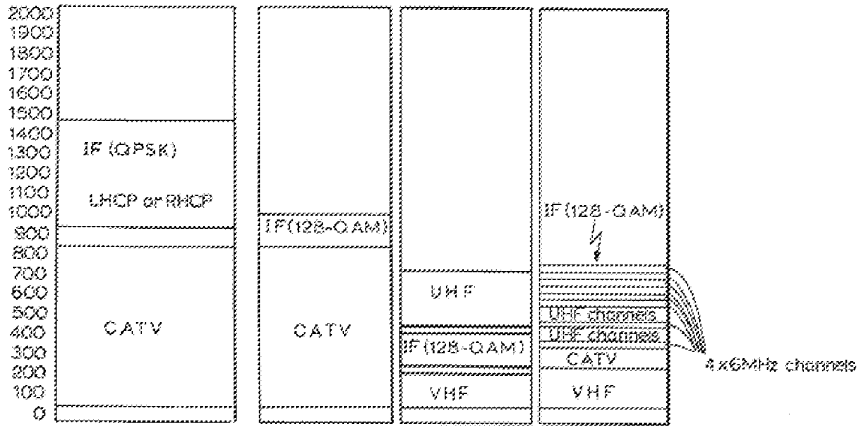
Asserted Claims	Williams '419
	signals. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 13:13–37: Furthermore, while the signal distribution system 10 is described herein as using a 128-QAM modulator 102, any other type of QAM modulator, such as an 8-QAM, 32-QAM, or higher order QAM modulator can be used to encode the decoded satellite signal, with the choice being dependent on how much frequency spectrum is available on a particular cable system and on how noisy the cable network tends to be which, in turn, drives the level of error protection required. In general, the higher the order of QAM encoding, the less frequency spectrum will be necessary to transmit the desired number (e.g., 32) satellite transponder signals (or other signals) over a cable network. However, the higher the order of QAM modulation, the more the transmodulated signals will be susceptible to noise while being transmitted over a cable network. Likewise, different ones of the transmodulator channels of FIG. 3 may transmodulate the received PM signal, i.e., the tuned transponder signal, using different modulation schemes. For example, a first set of the transmodulator channels may remodulate PM signals using a 128-QAM modulation

Asserted Claims	Williams '419
	technique, while a second set of transmodulator channels may use a 32-QAM modulation technique, a 64-QAM modulation technique, and so on. The choice of the modulation technique for any particular transmodulator channel may depend on, for example, the data rate of the PM signal being received, as well as other factors. Williams '419 at 13:38–54: Furthermore, as noted above, modulation techniques besides QAM can be used when transmodulating the decoded satellite signal. Other such modulation techniques may include, for example, any high rate digital modulation techniques such as VSB (vestigial side band), including 8-VSB, 16-VSB etc., or QAM with trellis-coded modulation. Other modulation techniques which may be developed in the future could similarly be used without departing from the spirit and scope of the present invention. In general, the choice of a modulation technique will be driven by the reduction in bandwidth which must be accomplished by the modulation technique and by the noise susceptibility of the modulation technique. If a different modulation technique is used, however, it is understood that a different type of cable encoder will be necessary to properly transmodulate the desired transponder signals (or other received signals) for propagation over the cable network 26. Williams '419 at 13:55–14:3: Likewise, it is understood that signals other than QPSK modulated signals can be received at the main signal receiver 14 (or other receiver) and transmodulated for delivery over the cable network 26 using the concepts described herein. In this situation, the particulars of the transmodulator 20 will change based on the type of modulation, carrier frequencies and transmission formats associated with these different received signals. It is considered that the use of an 8-PSK (phase shift keying) modulation scheme for encoding the satellite signal and a 16-QAM or higher order QAM (32-QAM, 64-QAM etc.) scheme for encoding the cable signal may be one useful combination. It is also considered that the use of a 16-QAM scheme for encoding the satellite signal and a 32-QAM or higher order QAM scheme for encoding the cable signal may be another useful combination.

Asserted Claims	Williams '419
	Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 1:

Asserted Claims	Williams '419
	 FIG. 1 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
10. The signal distribution system of claim 9 wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output.	Williams '419 discloses, explicitly and/or inherently, wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output. *See* claim 9, *supra*. *See, e.g.*: Williams '419 at 1:29–43:

Asserted Claims	Williams '419
	Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between



Asserted Claims	Williams '419
	about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the

Asserted Claims	Williams '419
	transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate

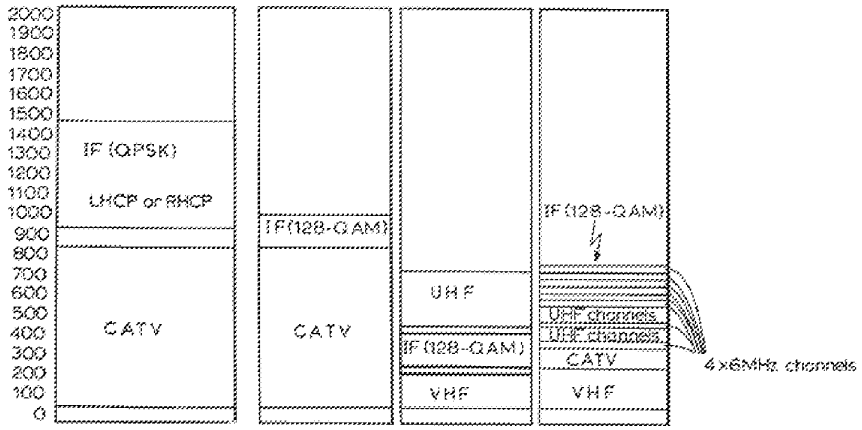
Asserted Claims	Williams '419
	frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals.

Asserted Claims	Williams '419
	Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62:

Asserted Claims	Williams '419
	If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error

Asserted Claims	Williams '419
	during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 2:  FIG. 2 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
11. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the gateway and the translation	Williams '419 discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the gateway and the translation table is communicated to devices in the network.

Asserted Claims	Williams '419
table is communicated to devices in the network.	*See* claim 10, *supra*. *See, e.g.*: Williams '419 at 1:29–43: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units.



Asserted Claims	Williams '419
	Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and

Asserted Claims	Williams '419
	correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band.

Asserted Claims	Williams '419
	Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network

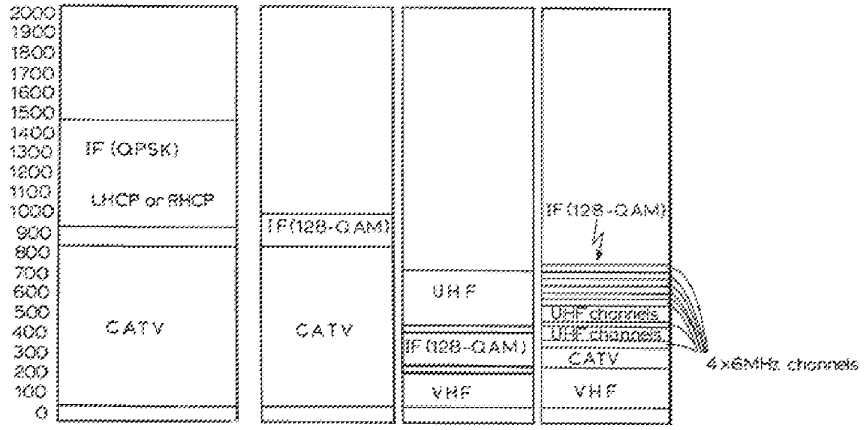
Asserted Claims	Williams '419
	26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43:

Asserted Claims	Williams '419
	The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM

Asserted Claims	Williams '419
	demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 2:  FIG. 2

Asserted Claims	Williams '419
	To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
12. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network.	Williams '419 discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network. *See* claim 10, *supra*. *See, e.g.*: Williams '419 at 1:29–43: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '419 at 1:60–2:10: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in operation

Asserted Claims	Williams '419
	uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '419 at 2:11–21: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '419 at 2:22–40: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g. between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as



Asserted Claims	Williams '419
	RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '419 at 6:8–27: The transmodulator 20 remodulates or transmodulates the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to, for example, a single band of 192 MHz. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '419 at 7:47–61: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency

Asserted Claims	Williams '419
	distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 750 MHz without significant degradation. Williams '419 at 8:42–50: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to base-band. Williams '419 at 9:12–24: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of eight summers 64 associated with the transmodulator 20. Williams '419 at 9:25–40: In the configuration of FIG. 3, each of the summers 64 receives an input from four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of the eight groups of four, 6 MHz-wide transmodulated signals illustrated in the right-most column of FIG. 2. The eight summers 64 of FIG. 3 provide eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the eight groups of four, 6 MHz-wide signals to a different carrier

Asserted Claims	Williams '419
	frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '419 at 9:41–55: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g. local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Preferably, such transmodulated terrestrial signals will be transmodulated to the same modulation scheme as the transmodulated satellite signals to simplify decoding of the transmodulated terrestrial signals. Williams '419 at 10:1–27: In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the 32 transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and

Asserted Claims	Williams '419
	gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '419 at 10:34–43: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the 32 transmodulated signals and, if so, identify that band for use by a specific one or more of the transponder signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all 32 of the transmodulated signals. Williams '419 at 10:44–62: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired (e.g., 32) transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the 32 transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for

Asserted Claims	Williams '419
	elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '419 at 14:27–54: The IRD 30 includes a down-converter and tuner 110 connected to the cable network 26. The down-converter is used, if necessary, to shift higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. The tuner 110 is responsive to a controller (not shown) and tunes to the frequency band associated with a selected one of the 6 MHz-wide transmodulated signals. The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '419 at Fig. 2:

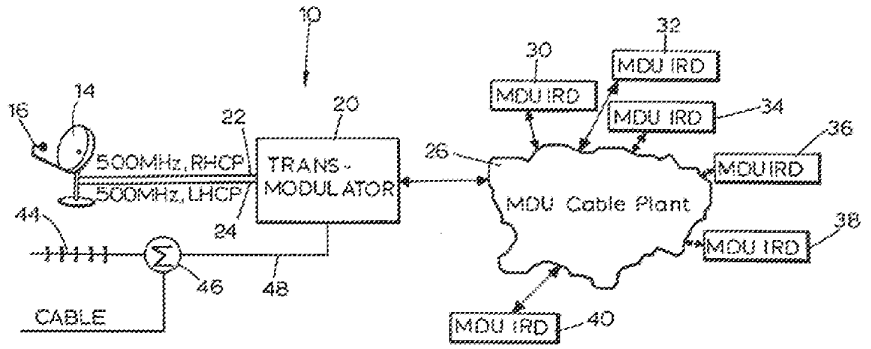
Asserted Claims	Williams '419
	 FIG. 2 To the extent Williams '419 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '419 alone or it would have been obvious to combine Williams '419 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

INVALIDITY CLAIM CHART[1]
Invalidity of U.S. Patent No. 7,542,715 in view of Williams '873

U.S. Patent No. 6,493,873 ("Williams '873") was filed on January 20, 1998 and issued on December 10, 2002. Williams '873 therefore qualifies as prior art to the '715 patent under, at least, (pre-AIA) 35 U.S.C. § 102(a) and/or (e). For the reasons listed below, Williams '873 invalidates the asserted claims of the '715 patent under 35 U.S.C. §§ 102 or 103 alone, in view of the knowledge of one of skill in the art, or in combination with various prior art references identified in the chart, as discussed below, in Appendix B, or with one or more references identified in Defendants' Invalidity Contentions. References to figures, drawings, and the like refer to the cited items as well as any accompanying or related text.

Asserted Claims	Williams '873
9[pre] 9. A signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU) comprising:	Defendants take no position in these Invalidity Contentions on whether the entirety of the preamble of this claim is a limitation. To the extent it is a limitation, Williams '873 discloses, explicitly and/or inherently, a signal distribution system for distributing a plurality of low noise amplifier and block converter (LNB) output signals from a satellite outdoor unit (ODU). *See, e.g.*: Williams '873 at Abstract:

[1] Defendants apply the prior art in light of Plaintiff's improper assertions of infringement and improper application of the claims. Defendants do not agree with Plaintiff's application of the claims, or that the claims satisfy 35 U.S.C. § 112. In the invalidity contentions cover pleading, Defendants identified terms in the '715 patent that it contends are governed by 35 U.S.C. § 112(6). While the charts below identify where certain elements are found in the prior art, including the identity of structures, acts or materials in each item of prior art that perform the function for terms governed by 35 U.S.C. § 112(6), Defendants' contentions herein are not, and should in no way be seen as, admissions or adoptions as to any particular claim scope or construction, or as any admission that any particular element is met in any particular way. Defendants object to any attempt to imply claim construction from this chart. Defendants' prior art invalidity contentions are made in a variety of alternatives and do not represent Defendants' agreement or view as to the meaning, definiteness, written description support for, or enablement of any claim contained therein.



Asserted Claims	Williams '873
	A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 2:15–25: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '873 at 2:26–44: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g., between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because

Asserted Claims	Williams '873
	cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '873 at 2:45–59: Furthermore, the receiving antennas or dishes associated with land-based or satellite-based wireless signal distribution systems are typically large and cumbersome. For example, C-band satellite dishes are generally in the range of four to five feet in diameter and, therefore, require a large amount of operating space. As a result, it can be difficult, if not practically impossible, to install a receiving antenna for each individual unit within a multiple dwelling unit (MDU), such as an apartment, condominium or townhome complex. Reception of a particular satellite signal is made even more difficult in MDUs when, as is generally the case, some of the individual dwelling units therein do not have any walls or outside exposure facing the direction in which the receiving antenna must be pointed, or these dwelling units are shadowed by surrounding buildings or other obstructions. Williams '873 at 3:13–32: One system proposed by the European Telecommunications Standards Institute (ETSI) in the area of Satellite Master Antenna Television (SMATV) receives a QPSK modulated satellite television signal (which may be combined with terrestrial TV signals) and remodulates this signal according to a 64 quadrature amplitude modulation (64-QAM) technique. The SMATV system then sends this remodulated signal out over cable to one or more adjacent buildings. Likewise, U.S. Pat. No. 5,173,775 discloses a system that remodulates data portions of a satellite television signal from one modulation scheme to another, such as from FM to AM, for retransmission to subscribers. However, these systems do not specifically demonstrate how to propagate remodulated satellite signals and existing cable or terrestrial signals on the same cable line or other transmission channel in an efficient manner or demonstrate how to remodulate and broadcast a large number of

Asserted Claims	Williams '873
	transponder signals associated with one or more satellites over the same cable line or other transmission channel to one or more adjacent buildings. Williams '873 at 3:33–47: The above-identified parent application discloses a signal redistribution system that transmodulates each of, for example, 32 received satellite transponder signals into a different modulation scheme and transmits each of these transmodulated signals, along with standard terrestrial signals, to each of a set of receivers within an MDU. The transmodulator disclosed in this application includes a separate channel having a satellite signal demodulator coupled to a signal remodulator for each of the received satellite transponder signals. As a result, this transmodulator unit tends to be expensive, especially when used in an MDU which includes fewer satellite signal receivers or subscribers than there are channels in the transmodulator unit, i.e., in MDUs that will never need all of the channels provided by the transmodulator unit. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which

Asserted Claims	Williams '873
	uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 5:59–6:11: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 6:12–34: The transmodulator 20 remodulates or transmodulates a subset of the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to any lower bandwidth. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes and/or by remodulating less than all of the received transponder signals associated with the composite signal. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal having less than all of the received transponder signals on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute

Asserted Claims	Williams '873
	the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the

Asserted Claims	Williams '873
	transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at Fig. 1:  FIG. 1 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Asserted Claims	Williams '873
9[a] a gateway in communication with the ODU and at least one set top box (STB);	Williams '873 discloses, explicitly and/or inherently, a gateway in communication with the ODU and at least one set top box (STB). *See, e.g.*: Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 3:33–47: The above-identified parent application discloses a signal redistribution system that transmodulates each of, for example, 32 received satellite transponder signals into a different modulation scheme and transmits each of these transmodulated signals, along with standard terrestrial signals, to each of a set of receivers within an MDU. The transmodulator disclosed in this application includes a separate channel having a satellite signal demodulator coupled to a signal remodulator for each of the received satellite transponder signals. As a result, this transmodulator unit tends to be expensive, especially when used in an MDU which includes fewer satellite signal receivers or subscribers than there are channels in the transmodulator unit, i.e., in MDUs that will never need all of the channels provided by the transmodulator unit.

Asserted Claims	Williams '873
	Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 4:4–15: According to another aspect of the present invention, a signal distribution system adapted to receive a composite signal having a multiplicity of transponder signals therein includes a transmodulator that transmodulates a selected one of the transponder signals from a first modulation scheme to a second modulation scheme to produce a transmodulated signal and a transmitter that transmits the transmodulated signal over a communication channel to a plurality of individual receivers. A receiver receives a request signal from each of the plurality of individual receivers and a controller selects the selected transponder signal in response to the request signals. Williams '873 at 4:16–38:

Asserted Claims	Williams '873
	According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 4:45–59: The signal distribution system may include a second receiver adapted to receive a terrestrial signal while the combiner may combine the multiplicity of transmodulated signals with the terrestrial signal to produce the combined signal. Furthermore, a reception device coupled to the communication channel at one of the individual receivers may include a receiver that receives the combined signal, a demodulator that demodulates a portion of the received combined signal and an individual transmitter that transmits one of the request signals to the transmodulator indicating one of the plurality of program multiplex signals to be transmodulated. If desired, the transmodulator channels may transmodulate between a quadrature phase shift keying (QPSK) modulation scheme and a quadrature amplitude modulation (QAM) scheme, such as a 128-QAM scheme. Williams '873 at 5:59–6:11:

Asserted Claims	Williams '873
	The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 6:12–34: The transmodulator 20 remodulates or transmodulates a subset of the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to any lower bandwidth. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes and/or by remodulating less than all of the received transponder signals associated with the composite signal. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal having less than all of the received transponder signals on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the

Asserted Claims	Williams '873
	transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the

Asserted Claims	Williams '873
	transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 9:28–39: In accordance with the present invention, the number of transmodulator channels is less than the number of transponder signals associated with the received satellite or other signal and, in a preferred embodiment, the transmodulator 20 includes up to, but less than, 32 transmodulator channels, each of which includes a switch 53, a tuner 54, a satellite decoder 56, a packetizer 58, a cable encoder 60, and an upconverter 62. Each transmodulator channel decodes and transmodulates one of the 32 received transponder signals associated with the downlink signal in essentially the same manner and, as a result, the operation of only one of the transmodulator channels will be described herein. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches

Asserted Claims	Williams '873
	53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator channels to tune to a specific one of the selected transponder signals. The control unit 72 may assign the transmodulator channels to tune to different transponder signals on a first come, first serve basis, by determining which of the transponder signals have the highest number of active requests associated therewith or using any other desired technique. Williams '873 at 11:22–35: If desired, the control unit 72 may provide a signal via side data to each of the IRDs 30-40 specifying which transponder signals are being transmodulated and transmitted over the cable network 26 and the frequencies at which the transmodulated transponder signals are located on the cable network 26. Also, if desired, when the control unit 72 receives

Asserted Claims	Williams '873
	requests for more transponder signals than there are transmodulator channels, the control unit 72 may send a signal to one or more of the IRDs 30-40 indicating that the requested signal cannot be decoded at, the present time because all of the transmodulator channels are being used to transmodulate other transponder signals. This communication may be performed using the cable network 26 or using any other wire or wireless network. Williams '873 at 14:26–37: While the transmodulator 20 is described herein as including a packetizer 58 which repacketizes 130 byte data packets produced by a standard DSS satellite decoder 56 into standard 188 byte data packets used by systems following the DVB transmission standard to enable the use of known DSS satellite decoders and known DVB cable encoders, the transmodulator 20 could, instead, include circuitry specifically designed to encode the 130 byte data packets produced by the satellite decoder 56 in a manner similar to the DVB cable encoder, i.e., by scrambling, R-S encoding, interleaving, etc. the 130 byte data packets to produce the 128-QAM modulated signals. Williams '873 at 14:38–64: Furthermore, while the signal distribution system 10 is described herein as using a 128-QAM modulator 102, any other type of QAM modulator, such as an 8-QAM, 16-QAM, 32-QAM, 64-QAM or higher order QAM modulator can be used to encode the decoded satellite signal, with the choice being dependent on how much frequency spectrum is available on a particular cable system, on how noisy the cable network tends to be which, in turn, drives the level of error protection required and on how many transmodulated signals are being delivered to the receiver units. In general, the higher the order of QAM encoding, the less frequency spectrum will be necessary to transmit the desired number satellite transponder signals (or other signals) over a cable network. However, the higher the order of QAM modulation, the more the transmodulated signals will be susceptible to noise while being transmitted over a cable network. Likewise, different ones of the transmodulator channels of FIG. 3 may transmodulate the received PM signal, i.e., the tuned transponder signal, using different modulation schemes. For example, a first set of

Asserted Claims	Williams '873
	the transmodulator channels may remodulate PM signals using a 128-QAM modulation technique, while a second set of transmodulator channels may use a 32-QAM modulation technique, a 64-QAM modulation technique, and so on. The choice of the modulation technique for any particular transmodulator channel may depend on, for example, the data rate of the PM signal being received, as well as other factors. Williams '873 at 15:15–27: Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at 15:28–45: Likewise, it is understood that signals other than QPSK modulated signals can be received at the main signal receiver 14 (or other receiver) and transmodulated for delivery over the cable network 26 using the concepts described herein. In this situation, the particulars of the transmodulator 20 will change based on the type of modulation, carrier frequencies and transmission formats associated with these different received signals. It is considered that the use of an 8-PSK (phase shift keying) modulation scheme for encoding the satellite signal and a 16-QAM or higher order QAM (32-QAM, 64-QAM etc.) scheme for encoding the cable signal may be one useful combination. It is also considered that the use of a 16-QAM scheme for encoding the satellite signal and a 32-QAM or higher order QAM scheme for encoding the cable signal may be another useful combination. Williams '873 at 15:53–16:4:

Asserted Claims	Williams '873
	The IRD 30 may initially scan all the channels from, for example, low carrier frequencies to high carrier frequencies, to locate the frequency bands or channels used by the selected ones of the transmodulated signals and then assign channel numbers to these located signals based on a predetermined ordering scheme used by the transmodulator 20. However, as noted above, the transmodulator 20 may actively signal the channel locations, ordering, frequency assignments, etc. of the transmodulated satellite signals and/or terrestrial signals via a communication channel (using side data) established over, for example, the cable network 26. Such a communication channel may comprise a low-speed channel that uses uncoded bits of the sync and error code bytes within the, for example, 188 byte data packets, and may be used to deliver any desired information to the IRD 30 over time, i.e., using a large number of the 188 byte data packets. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

Asserted Claims	Williams '873
9[b] a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information;	Williams '873 discloses, explicitly and/or inherently, a signal selector that receives a plurality of broadband LNB signals comprising a plurality of transponder signals, the signal selector is responsive to transponder select information transmitted by the gateway and selects a plurality of transponder signals from at least one broadband LNB signal based on the transponder select information. *See, e.g.*: Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard

Asserted Claims	Williams '873
	terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 4:4–15: According to another aspect of the present invention, a signal distribution system adapted to receive a composite signal having a multiplicity of transponder signals therein includes a transmodulator that transmodulates a selected one of the transponder signals from a first modulation scheme to a second modulation scheme to produce a transmodulated signal and a transmitter that transmits the transmodulated signal over a communication channel to a plurality of individual receivers. A receiver receives a request signal from each of the plurality of individual receivers and a controller selects the selected transponder signal in response to the request signals. Williams '873 at 4:39–44: Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 6:35–46: In order to determine which of the received satellite transponder signals should be transmodulated at any particular time, the transmodulator 20 receives and decodes requests for particular channels or satellite signals from each of the IRDs 30-40 that are active, determines from these requests which of the set of satellite or transponder signals to transmodulate and then tunes to and transmodulates only those selected satellite or

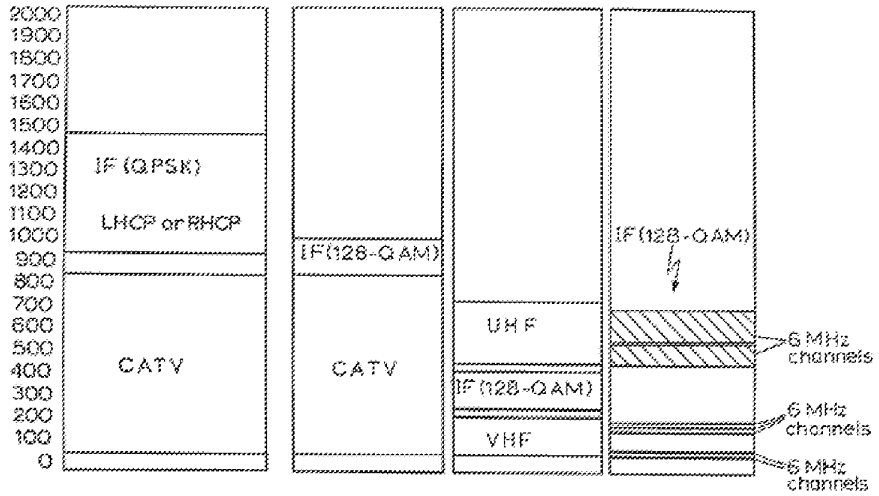
Asserted Claims	Williams '873
	transponder signals. The transmodulator sends the updated frequency index to the receiver via side data. If no transponders are available to fulfill the request, the transmodulator sends an error message to the receiver indicating that no transponder is available. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire

Asserted Claims	Williams '873
	network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator channels to tune to a specific one of the selected transponder signals. The control unit 72 may assign the transmodulator channels to tune to different transponder signals on a first come, first serve basis, by determining which of the transponder signals have the highest number of active requests associated therewith or using any other desired technique. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals,

Asserted Claims	Williams '873
	as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:1–6: After the control unit 72 identifies all of the empty or unused frequency bands, this information is preferably stored in non-volatile memory. Operator selection (e.g., by means of a keypad) may also be utilized to select or de-select frequency bands, either alone or in conjunction with an automated system. To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873

Asserted Claims	Williams '873
	with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[c] a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals; and	Williams '873 discloses, explicitly and/or inherently, a frequency translator coupled to the signal selector that is capable of shifting the selected transponder signals to new carrier frequencies to produce RF signals. *See, e.g.*: Williams '873 at 1:32–46: Some wireless signal distribution systems use one or more geosynchronous satellites to broadcast a broadband A-V signal to receiving units within a large geographic area while other wireless systems are land-based, using one or more land-based transmitters to broadcast to individual receiver units within smaller geographic areas or cells. A satellite A-V signal distribution system generally includes an earth station that compiles a number of individual A-V programs into a broadband signal, modulates a carrier frequency band with the broadband signal and then transmits (uplinks) the modulated signal to one or more geosynchronous satellites. The satellites amplify the received signals, shift the signals to different carrier frequency bands and transmit (downlink) the frequency shifted signals to earth for reception at individual receiving units. Williams '873 at 1:64–2:14: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in-operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz, and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder

Asserted Claims	Williams '873
	signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '873 at 2:15–25: At the individual receiver units, a receiving antenna, typically comprising a parabolic dish antenna, is pointed in the general direction of the transmitting satellite (or other transmitting location) to receive the broadband QPSK modulated multiplex of A-V signals. Typically, such antennas include a low noise block (LNB) which amplifies, filters and shifts the incoming signal to an intermediate frequency band, such as L-band (between about 1.0 GHz and 2.0 GHz). The representative system, in particular, shifts the satellite signal to the frequency band between about 950 MHz and about 1450 MHz. Williams '873 at 2:26–44: Typically, only the RHCP transponder signals or the LHCP transponder signals are mixed down to L-band, depending on which particular A-V channel a user is viewing. However, in systems having a two-channel LNB, both the RHCP and the LHCP transponder signals may be individually shifted down to a 500 MHz portion of L-band (e.g., between 950 MHz and 1450 MHz) and provided, via separate lines, to a set-top box or other integrated receiver and detector (IRD) associated with the receiver unit. At the IRD, an A-V program associated with a particular channel within one of the program-multiplexed transponder signals is decoded and provided to a television or other presentation or processing device for display and/or for processing of transmitted data, audio output, etc. However, because cable lines are inherently frequency limited, typical cables used at receiver sites (such as RG-6 and RG-59) are not capable of simultaneously transmitting all of the received satellite signals (1000 MHz) along with standard CATV signals to the IRD. Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V



Asserted Claims	Williams '873
	channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 8:20–35: The third left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places one or more of the 32, 6 MHz-wide, 128-QAM-modulated signals at a frequency band between approximately 222 MHz and 414 MHz between the CATV or other signals at the VHF and UHF bands. In this case, the transmodulator 20 may need to select which terrestrial (e.g., CATV) signals should be placed in the available portions of the UHF band above about 450 MHz and in the available portions of the VHF band below about 200 MHz and may need to shift some or all of the chosen terrestrial signals to those bands before placing the transmodulated signals on the cable network 26. This frequency distribution technique is useful in lower quality cable systems that propagate signals at frequencies up to about 550 or perhaps 750 MHz without significant degradation. Williams '873 at 9:40–48:

Asserted Claims	Williams '873
	The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:10–23: The DVB cable encoder 60, which may comprise any known DVB encoder module, modulates the received stream of 188 byte DVB data packets using, preferably, a 128-QAM modulation technique, to produce a 6 MHz-wide transmodulated signal including all of the audio-visual programs associated with one of the 32 original transponder signals. The 6 MHz-wide transmodulated signal developed by the cable encoder 60 is provided to an upconverter 62 which shifts the 6-MHz wide transmodulated signal to an intermediate frequency (IF), preferably comprising one of four different carrier IFs used by the transmodulator 20. The upconverter 62 then provides the IF signal to one of a number of summers 64 associated with the transmodulator 20. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1.

Asserted Claims	Williams '873
	Williams '873 at 10:40–52: The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g., local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:36–67:

Asserted Claims	Williams '873
	The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:17–34: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the transmodulated signals. In the case in which one or more of the terrestrial signals or the

Asserted Claims	Williams '873
	satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '873 at 15:15–27: Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners.

	Williams '873 at Fig. 2:  FIG. 2 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[d] a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal;	Williams '873 discloses, explicitly and/or inherently, a signal combiner coupled to at least one frequency translator capable of combining at least two RF signals to produce a composite signal. *See, e.g.*:

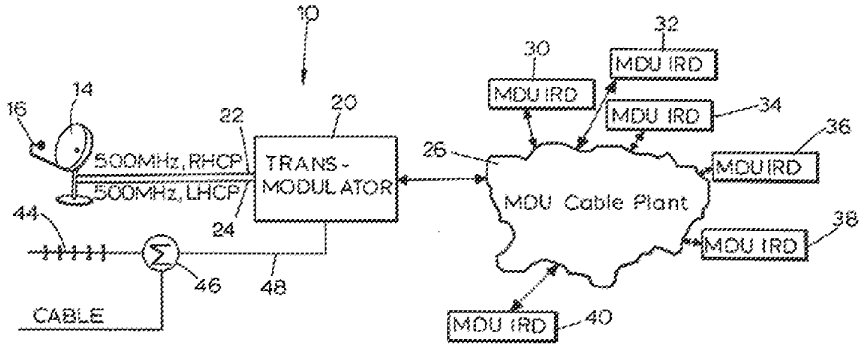
Asserted Claims	Williams '873
	Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which uses these requests to select Which of the portions of the broadband signal will be transmodulated.

Asserted Claims	Williams '873
	Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 4:39–44: Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 4:45–59: The signal distribution system may include a second receiver adapted to receive a terrestrial signal while the combiner may combine the multiplicity of transmodulated signals with the terrestrial signal to produce the combined signal. Furthermore, a reception device coupled to the communication channel at one of the individual receivers may include a receiver that receives the combined signal, a demodulator that demodulates a

Asserted Claims	Williams '873
	portion of the received combined signal and an individual transmitter that transmits one of the request signals to the transmodulator indicating one of the plurality of program multiplex signals to be transmodulated. If desired, the transmodulator channels may transmodulate between a quadrature phase shift keying (QPSK) modulation scheme and a quadrature amplitude modulation (QAM) scheme, such as a 128-QAM scheme. Williams '873 at 5:30–44: By the way of example only, the signal distribution system of the present invention is described herein as redistributing a broadband Ku-band satellite signal (comprising up to 32, QPSK-modulated transponder signals transmitted from one or more satellites at a carrier frequency band centered around approximately 12.45 GHz) to receiver units within an MDU. It is understood however, that the signal distribution system of the present invention can be used to redistribute any other type of satellite or land-based wireless signal. The term program multiplex (PM) signal is used herein to describe any single or multiplex of purely visual (such as video), purely audio, or purely data signals as well as a signal comprising any combination of audio, visual, data or other signals including, for example, television signals, digital data signals, etc. Williams '873 at 7:48–8:8: Referring now to FIG. 2, representative methods of combining the transmodulated transponder signals along with terrestrial signals on the cable network 26 are illustrated. The left-most column of FIG. 2 illustrates a previously known method of placing QPSK-modulated signals along with terrestrial signals on a cable network. According to this scheme, all existing terrestrial signals (including cable TV signals) are distributed at, for example, VHF and UHF carrier frequencies below 950 MHz while one of the 500 MHz-wide QPSK-modulated signals (associated with either the LHCP or the RHCP component of the satellite signal) is placed directly on the cable network at the unused band between about 950 MHz and 1450 MHz. A major problem with this configuration is that only the RHCP or the LHCP transponder signals can be placed on a 1450 MHz capable cable network at any given time which, in turn, prevents IRDs within an MDU from decoding or

Asserted Claims	Williams '873
	receiving channels associated with the other of the LHCP or the RHCP transponder signals. While this problem can be overcome by running two cable lines throughout an MDU or by utilizing a high frequency cable plant capable of approximately 2 GHz or greater bandwidth, these solutions require additional equipment and expense and are not adaptable to most existing cable plants now in use. Furthermore, the signals provided at the 950 MHz to 1450 MHz band can be severely degraded by the cable plant due to the poor high frequency propagation properties of many existing cable plants, especially older cable plants. Williams '873 at 8:9–19: The three right-most columns of FIG. 2 illustrate methods of combining selected ones of the 32, 6 MHz-wide, 128-QAM-modulated signals with existing terrestrial signals on the cable network 26. The second left-most column of FIG. 2 illustrates a configuration in which the transmodulator 20 places one or more of the 32, 6 MHz-wide, 128-QAM-modulated signals within a band between about 804 MHz and 996 MHz directly above the common CATV channels. This configuration can be used with higher grade cable networks that propagate signals at up to 1000 MHz without significant degradation. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1.

Asserted Claims	Williams '873
	To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
9[e] wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs.	Williams '873 discloses, explicitly and/or inherently, wherein the modulation of the composite signal is the same as the modulation of the broadband LNB signals and wherein the composite signal is transmitted to the gateway and the gateway receives the composite signal, decodes specific programs, and distributes the programs over a digital local area network (LAN) to STBs. *See, e.g.*: Williams '873 at Abstract: A system for redistributing a broadband audio-visual-data signal to a multiplicity of receiver units within a multiple dwelling unit (MDU) includes a main receiving antenna that receives a broadband video/audio/data signal having a number of individual program multiplex signals therein and a transmodulator device that transmodulates a selected subset of the individual program multiplex signals associated with the broadband signal from a first modulation scheme to a second modulation scheme. The transmodulated signals are broadcast over a cable network, along with terrestrial signals, to individual receiver units at the MDU. The receiver units send requests for user-selected ones of the individual program multiplex signals to the transmodulator device, demodulate the transmodulated and/or terrestrial signals and provide user-specified channels to television sets for display. Williams '873 at 1:13–18: The present invention relates generally to signal distribution systems and, more particularly, to audio/visual/data signal distribution systems that distribute satellite signals



Asserted Claims	Williams '873
	typically in conjunction with standard terrestrial and/or cable signals to a plurality of individual receivers within one or more multiple dwelling units. Williams '873 at 3:50–4:3: The present invention relates to a low cost system and method for distributing a set of program multiplexed A-V signals and, possibly, existing terrestrial signals, to a multiplicity of receiver units within one or more MDUs using an MDU cable network or other transmission channel. According to one aspect of the present invention, a receiving antenna receives a broadband signal from, for example, a satellite or a land-based transmitter. A transmodulator transmodulates selected portions of the broadband signal into a transmodulated signal having a bandwidth that is smaller than that of the received broadband signal and transmits this transmodulated signal, typically along with standard terrestrial signals, over a communication channel, such as a cable or a wireless network, to a number of individual receiver units within an MDU. The receiver units demodulate the received transmodulated signal and provide user-specified channels to processing or display units, e.g., video displays, television sets, audio systems, computers, etc. The receiver units also send requests for user-selected channels to the transmodulator which uses these requests to select Which of the portions of the broadband signal will be transmodulated. Williams '873 at 4:4–15: According to another aspect of the present invention, a signal distribution system adapted to receive a composite signal having a multiplicity of transponder signals therein includes a transmodulator that transmodulates a selected one of the transponder signals from a first modulation scheme to a second modulation scheme to produce a transmodulated signal and a transmitter that transmits the transmodulated signal over a communication channel to a plurality of individual receivers. A receiver receives a request signal from each of the plurality of individual receivers and a controller selects the selected transponder signal in response to the request signals.

Asserted Claims	Williams '873
	Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 4:39–44: Moreover, the signal distribution system generates an information signal, known as side data, which may include channel set-up information, frequency index set-up information, etc. This information signal is used by the receiver to select a requested signal from the plurality of individual program multiplex signals. Williams '873 at 4:45–59: The signal distribution system may include a second receiver adapted to receive a terrestrial signal while the combiner may combine the multiplicity of transmodulated signals with the terrestrial signal to produce the combined signal. Furthermore, a reception device coupled to the communication channel at one of the individual receivers may include a receiver that receives the combined signal, a demodulator that demodulates a

Asserted Claims	Williams '873
	portion of the received combined signal and an individual transmitter that transmits one of the request signals to the transmodulator indicating one of the plurality of program multiplex signals to be transmodulated. If desired, the transmodulator channels may transmodulate between a quadrature phase shift keying (QPSK) modulation scheme and a quadrature amplitude modulation (QAM) scheme, such as a 128-QAM scheme. Williams '873 at 4:60–5:5: According to a still further aspect of the present invention, a method of distributing a subset of a plurality of individual signals associated with a composite signal to multiple individual receivers includes the steps of receiving the composite signal, receiving a request signal from each of the individual receivers and choosing the subset of the plurality of the individual signals to be distributed based on the received request signals. Each of the subset of the plurality of the individual signals is transmodulated from a first modulation scheme to a second modulation scheme and is transmitted over a communication channel to the individual receivers. Williams '873 at 5:59–6:11: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a

Asserted Claims	Williams '873
	transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 9:28–39: In accordance with the present invention, the number of transmodulator channels is less than the number of transponder signals associated with the received satellite or other signal and, in a preferred embodiment, the transmodulator 20 includes up to, but less than, 32 transmodulator channels, each of which includes a switch 53, a tuner 54, a satellite decoder 56, a packetizer 58, a cable encoder 60, and an upconverter 62. Each transmodulator channel decodes and transmodulates one of the 32 received transponder signals associated with the downlink signal in essentially the same manner and, as a result, the operation of only one of the transmodulator channels will be described herein. Williams '873 at 10:40–52:

Asserted Claims	Williams '873
	The level shifter 70 may receive signals from an off-air antenna, from a cable provider and/or from any other desired signal source (e.g., local security or data services) and pass these signals through to the summer 68 at their current carrier frequency, or may shift these signals to one or more different carrier frequencies for propagation over the cable network 26 using any standard frequency translation or mixer circuitry. Of course, if desired, the level shifter 70 may include circuitry similar to the above-described transmodulator channels and transmodulate one or more of the received terrestrial signals to any desired modulation scheme, such as a 128-QAM scheme, for transmission over the cable network 26. Williams '873 at 14:65–15:14: Furthermore, as noted above, modulation techniques besides QAM can be used when transmodulating the decoded satellite signal. Other such modulation techniques may include, for example, any high rate digital modulation techniques such as VSB (vestigial side band), including 8-VSB, 16-VSB etc., or QAM with trellis-coded modulation. Other modulation techniques which may be developed in the future could similarly be used without departing from the spirit and scope of the present invention. In general, the choice of a modulation technique will be driven by the reduction in bandwidth which must be accomplished by the modulation technique and by the noise susceptibility of the modulation technique. If a different modulation technique is used, however, it is understood that a different type of cable encoder will be necessary to properly transmodulate the desired transponder signals (or other received signals) for propagation over the cable network 26. Williams '873 at 15:15–27: Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that

Asserted Claims	Williams '873
	it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at Fig. 1:  FIG. 1 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
10. The signal distribution system of claim 9 wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output.	Williams '873 discloses, explicitly and/or inherently, wherein a translation table maps original channel locations on the selector input to new channel locations on the selector output.

Asserted Claims	Williams '873
	See claim 9, *supra*. *See, e.g.*: Williams '873 at 1:64–2:14: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in-operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz, and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the

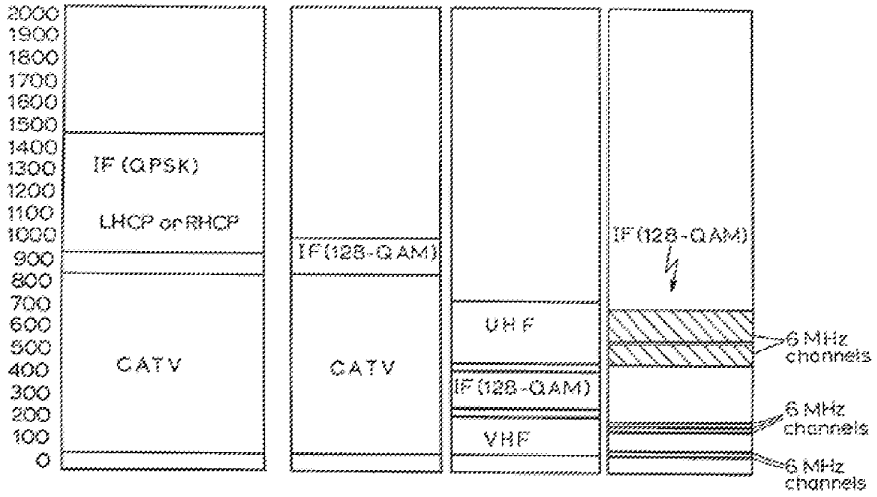
Asserted Claims	Williams '873
	individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate. Williams '873 at 5:59–6:11: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 6:12–34: The transmodulator 20 remodulates or transmodulates a subset of the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to any lower bandwidth. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes and/or by remodulating less than all of the received transponder signals associated with the composite signal. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal having less than all of the received transponder signals on a cable plant or cable network 26 within an MDU for distribution to

Asserted Claims	Williams '873
	a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '873 at 6:35–46: In order to determine which of the received satellite transponder signals should be transmodulated at any particular time, the transmodulator 20 receives and decodes requests for particular channels or satellite signals from each of the IRDs 30-40 that are active, determines from these requests which of the set of satellite or transponder signals to transmodulate and then tunes to and transmodulates only those selected satellite or transponder signals. The transmodulator sends the updated frequency index to the receiver via side data. If no transponders are available to fulfill the request, the transmodulator sends an error message to the receiver indicating that no transponder is available. Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20

Asserted Claims	Williams '873
	may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the

Asserted Claims	Williams '873
	transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 7:48–8:8: Referring now to FIG. 2, representative methods of combining the transmodulated transponder signals along with terrestrial signals on the cable network 26 are illustrated. The left-most column of FIG. 2 illustrates a previously known method of placing QPSK-modulated signals along with terrestrial signals on a cable network. According to this scheme, all existing terrestrial signals (including cable TV signals) are distributed at, for example, VHF and UHF carrier frequencies below 950 MHz while one of the 500 MHz-wide QPSK-modulated signals (associated with either the LHCP or the RHCP component of the satellite signal) is placed directly on the cable network at the unused band between about 950 MHz and 1450 MHz. A major problem with this configuration is that only the RHCP or the LHCP transponder signals can be placed on a 1450 MHz capable cable network at any given time which, in turn, prevents IRDs within an MDU from decoding or receiving channels associated with the other of the LHCP or the RHCP transponder signals. While this problem can be overcome by running two cable lines throughout an MDU or by utilizing a high frequency cable plant capable of approximately 2 GHz or greater bandwidth, these solutions require additional equipment and expense and are not adaptable to most existing cable plants now in use. Furthermore, the signals provided at the 950 MHz to 1450 MHz band can be severely degraded by the cable plant due to the poor high frequency propagation properties of many existing cable plants, especially older cable plants.

Asserted Claims	Williams '873
	Williams '873 at 9:28–39: In accordance with the present invention, the number of transmodulator channels is less than the number of transponder signals associated with the received satellite or other signal and, in a preferred embodiment, the transmodulator 20 includes up to, but less than, 32 transmodulator channels, each of which includes a switch 53, a tuner 54, a satellite decoder 56, a packetizer 58, a cable encoder 60, and an upconverter 62. Each transmodulator channel decodes and transmodulates one of the 32 received transponder signals associated with the downlink signal in essentially the same manner and, as a result, the operation of only one of the transmodulator channels will be described herein. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1.



Asserted Claims	Williams '873
	Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches 53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator channels to tune to a specific one of the selected transponder signals. The control unit 72 may assign the transmodulator channels to tune to different transponder signals on a first come, first serve basis, by determining which of the transponder signals have the highest number of active requests associated therewith or using any other desired technique. Williams '873 at 11:36–67:

Asserted Claims	Williams '873
	The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:1–6: After the control unit 72 identifies all of the empty or unused frequency bands, this information is preferably stored in non-volatile memory. Operator selection (e.g., by means of a keypad) may also be utilized to select or de-select frequency bands, either alone or in conjunction with an automated system. Williams '873 at 12:7–16:

Asserted Claims	Williams '873
	The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the transmodulated signals and, if so, identify that band for use by a specific one or more of the transmodulated signals by changing the output frequency of, for example, the upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all of the transmodulated signals. Williams '873 at 12:17–34: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '873 at 12:35–47: A transmodulator control panel 74 is coupled to the control unit 72 and, preferably, includes signal strength measurement devices that indicate the relative strength of each of the satellite signals and/or each of the terrestrial signals input to the transmodulator 20. The control panel 74 may also allow an operator to choose default frequency locations for each of the transmodulated and/or terrestrial signals and may include controls that permit an installer to select the carrier frequency bands for any number of the transmodulated and/or

Asserted Claims	Williams '873
	terrestrial signals. Of course, the transmodulator control panel 74 and the control unit 72 may perform any other desired functions with respect to the transmodulator 20. Williams '873 at 15:15–27: Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at 15:53–16:4: The IRD 30 may initially scan all the channels from, for example, low carrier frequencies to high carrier frequencies, to locate the frequency bands or channels used by the selected ones of the transmodulated signals and then assign channel numbers to these located signals based on a predetermined ordering scheme used by the transmodulator 20. However, as noted above, the transmodulator 20 may actively signal the channel locations, ordering, frequency assignments, etc. of the transmodulated satellite signals and/or terrestrial signals via a communication channel (using side data) established over, for example, the cable network 26. Such a communication channel may comprise a low-speed channel that uses uncoded bits of the sync and error code bytes within the, for example, 188 byte data packets, and may be used to deliver any desired information to the IRD 30 over time, i.e., using a large number of the 188 byte data packets. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and

Asserted Claims	Williams '873
	transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at 16:22--42: The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '873 at Fig. 2:

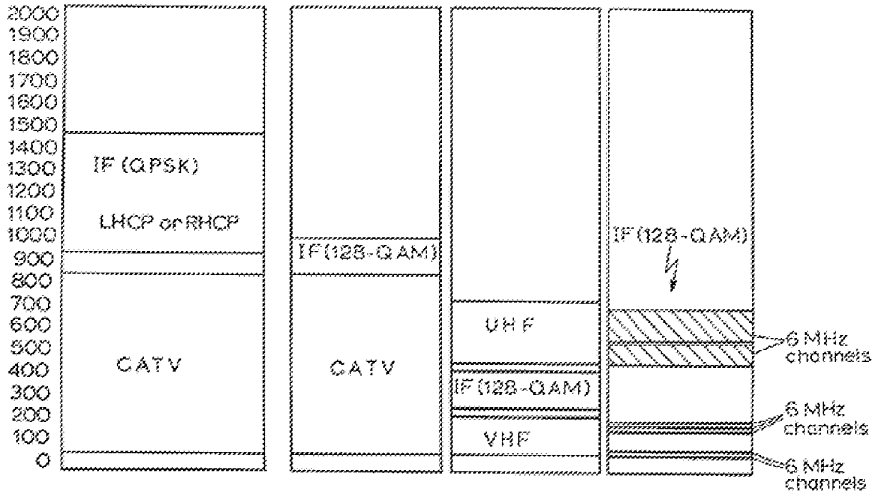
The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable

Asserted Claims	Williams '873
	network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other

Asserted Claims	Williams '873
	communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 7:48–8:8: Referring now to FIG. 2, representative methods of combining the transmodulated transponder signals along with terrestrial signals on the cable network 26 are illustrated. The left-most column of FIG. 2 illustrates a previously known method of placing QPSK-modulated signals along with terrestrial signals on a cable network. According to this scheme, all existing terrestrial signals (including cable TV signals) are distributed at, for example, VHF and UHF carrier frequencies below 950 MHz while one of the 500 MHz-wide QPSK-modulated signals (associated with either the LHCP or the RHCP component of the satellite signal) is placed directly on the cable network at the unused band between about 950 MHz and 1450 MHz. A major problem with this configuration is that only the RHCP or the LHCP transponder signals can be placed on a 1450 MHz capable cable network at any given time which, in turn, prevents IRDs within an MDU from decoding or receiving channels associated with the other of the LHCP or the RHCP transponder signals. While this problem can be overcome by running two cable lines throughout an MDU or by utilizing a high frequency cable plant capable of approximately 2 GHz or greater bandwidth, these solutions require additional equipment and expense and are not adaptable to most existing cable plants now in use. Furthermore, the signals provided at the 950 MHz to 1450 MHz band can be severely degraded by the cable plant due to the poor high frequency propagation properties of many existing cable plants, especially older cable plants. Williams '873 at 9:28–39: In accordance with the present invention, the number of transmodulator channels is less than the number of transponder signals associated with the received satellite or other signal

Asserted Claims	Williams '873
	and, in a preferred embodiment, the transmodulator 20 includes up to, but less than, 32 transmodulator channels, each of which includes a switch 53, a tuner 54, a satellite decoder 56, a packetizer 58, a cable encoder 60, and an upconverter 62. Each transmodulator channel decodes and transmodulates one of the 32 received transponder signals associated with the downlink signal in essentially the same manner and, as a result, the operation of only one of the transmodulator channels will be described herein. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches



Asserted Claims	Williams '873
	53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator channels to tune to a specific one of the selected transponder signals. The control unit 72 may assign the transmodulator channels to tune to different transponder signals on a first come, first serve basis, by determining which of the transponder signals have the highest number of active requests associated therewith or using any other desired technique. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which

Asserted Claims	Williams '873
	frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:1–6: After the control unit 72 identifies all of the empty or unused frequency bands, this information is preferably stored in non-volatile memory. Operator selection (e.g., by means of a keypad) may also be utilized to select or de-select frequency bands, either alone or in conjunction with an automated system. Williams '873 at 12:7–16: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the transmodulated signals and, if so, identify that band for use by a specific one or more of the transmodulated signals by changing the output frequency of, for example, the

Asserted Claims	Williams '873
	upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all of the transmodulated signals. Williams '873 at 12:17–34: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '873 at 12:35–47: A transmodulator control panel 74 is coupled to the control unit 72 and, preferably, includes signal strength measurement devices that indicate the relative strength of each of the satellite signals and/or each of the terrestrial signals input to the transmodulator 20. The control panel 74 may also allow an operator to choose default frequency locations for each of the transmodulated and/or terrestrial signals and may include controls that permit an installer to select the carrier frequency bands for any number of the transmodulated and/or terrestrial signals. Of course, the transmodulator control panel 74 and the control unit 72 may perform any other desired functions with respect to the transmodulator 20. Williams '873 at 15:15–27:

Asserted Claims	Williams '873
	Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at 15:53–16:4: The IRD 30 may initially scan all the channels from, for example, low carrier frequencies to high carrier frequencies, to locate the frequency bands or channels used by the selected ones of the transmodulated signals and then assign channel numbers to these located signals based on a predetermined ordering scheme used by the transmodulator 20. However, as noted above, the transmodulator 20 may actively signal the channel locations, ordering, frequency assignments, etc. of the transmodulated satellite signals and/or terrestrial signals via a communication channel (using side data) established over, for example, the cable network 26. Such a communication channel may comprise a low-speed channel that uses uncoded bits of the sync and error code bytes within the, for example, 188 byte data packets, and may be used to deliver any desired information to the IRD 30 over time, i.e., using a large number of the 188 byte data packets. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable

Asserted Claims	Williams '873
	network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at 16:22–42: The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '873 at Fig. 2:

Asserted Claims	Williams '873
	 FIG. 2 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.
12. The signal distribution system of claim 10 wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network.	Williams '873 discloses, explicitly and/or inherently, wherein the translation table is maintained by a controller located in the ODU and the translation table is communicated to devices in the network. *See* claim 10, *supra*. *See, e.g.*:

Asserted Claims	Williams '873
	Williams '873 at 1:64–2:14: Satellite signal distribution systems exist for many frequency bands, including the so-called "Ku-band." One known Ku-band direct-to-home satellite system now in-operation uses an uplink signal having 16 RHCP transponder signals and 16 LHCP transponder signals modulated onto frequency bands between about 17.2 GHz, and about 17.7 GHz. Each of these 32 transponder signals is program-multiplexed to include digital data packets associated with e.g. about five to eight or more individual A-V programs, such as television channels, and is modulated according to a quaternary phase shift keying (QPSK) modulation scheme. The satellites associated with this system shift the uplink transponder signals to carrier frequencies ranging from approximately 12.2 GHz to approximately 12.7 GHz and transmit these frequency-shifted transponder signals back to earth for reception at each of a plurality of individual receiver units. Williams '873 at 4:16–38: According to another aspect of the present invention, a signal distribution system for distributing a composite signal having a plurality of individual program multiplex signals therein over a communication channel to a number of individual receivers includes a main receiver that receives the composite signal and a multiplicity of transmodulator channels coupled to the main receiver. Each of the multiplicity of transmodulator channels, preferably numbering less than the number of individual program multiplex signals, transmodulates a different one of the plurality of individual program multiplex signals from a first modulation scheme to a second modulation scheme to produce one of a multiplicity of transmodulated signals. A combiner combines the multiplicity of transmodulated signals at different carrier frequency bands to produce a combined signal and a transmitter transmits the combined signal over the communication channel to the individual receivers. The signal distribution system also includes a request receiver that receives a request signal from each of the individual receivers and a controller coupled to the request receiver that controls which of the plurality of individual program multiplex signals each of the multiplicity of transmodulator channels is to transmodulate.

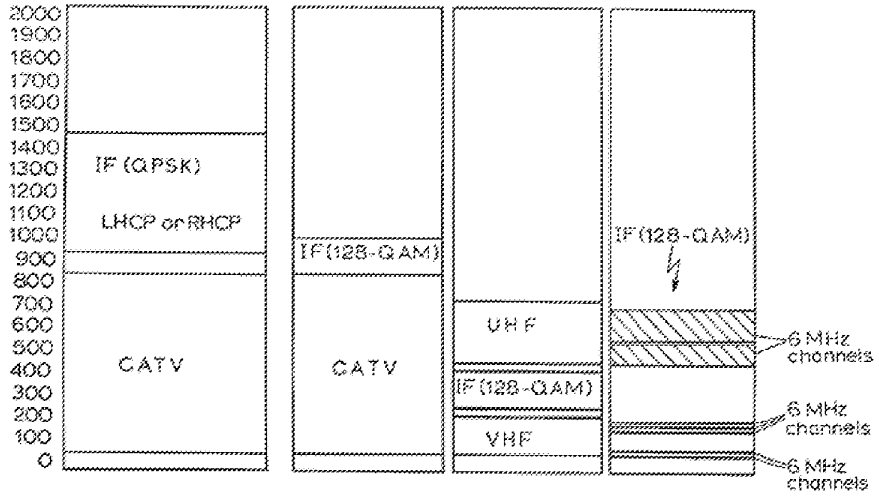
Asserted Claims	Williams '873
	Williams '873 at 5:59–6:11: The signal distribution system 10 includes a main signal receiver 14 disposed on, for example, the roof of an MDU or any other location capable of receiving a signal transmitted by a satellite or other signal source. The signal receiver 14 is preferably in the form of a 24-inch diameter parabolic dish antenna pointed towards, for example, satellites that transmit a Ku-band or other broadband, QPSK-modulated PM composite signal. A two-channel LNB 16 associated with the dish antenna 14 receives the modulated satellite signal reflected from the dish antenna 14. Each of the channels of the LNB 16 filters either the RHCP or the LHCP component of the received signal and mixes this filtered signal down to an intermediate frequency band, for example, the portion of L-band between 950 MHz and 1450 MHz. The LNB 16 amplifies and provides the 500 MHz, L-band signals associated with each of the RHCP and LHCP components of the downlink signal to a transmodulator 20 via lines 22 and 24, respectively. Other methods for providing the received QPSK input signals to the transmodulator 20 may also be used. Williams '873 at 6:12–34: The transmodulator 20 remodulates or transmodulates a subset of the signals received from the LNB 16 using an output modulation technique that, preferably, reduces the bandwidth of the signals received from the LNB 16 from two 500 MHz bands (i.e., a total of 1000 MHz) to any lower bandwidth. This reduction in bandwidth may be accomplished by utilizing a more aggressive encoding scheme with appropriate error detection and correction codes and/or by remodulating less than all of the received transponder signals associated with the composite signal. The transmodulator 20 then places the transmodulated, reduced-in-bandwidth signal having less than all of the received transponder signals on a cable plant or cable network 26 within an MDU for distribution to a number of IRDs 30, 32, 34, 36, 38 and 40 associated with individual receiver units spread throughout the MDU. The transmodulator 20 may instead, or in addition, distribute the transmodulated signals over wire or via any wireless communication channel (including, for example, microwave and optical systems) to head-ends at any other MDUs or local sites or portions thereof. Of course, the transmodulator 20 may also distribute the

Asserted Claims	Williams '873
	transmodulated signals directly to IRDs using any desired wireless communication channel. Williams '873 at 6:35–46: In order to determine which of the received satellite transponder signals should be transmodulated at any particular time, the transmodulator 20 receives and decodes requests for particular channels or satellite signals from each of the IRDs 30-40 that are active, determines from these requests which of the set of satellite or transponder signals to transmodulate and then tunes to and transmodulates only those selected satellite or transponder signals. The transmodulator sends the updated frequency index to the receiver via side data. If no transponders are available to fulfill the request, the transmodulator sends an error message to the receiver indicating that no transponder is available. Williams '873 at 6:47–7:3: The transmodulator 20 may also receive signals from a cable provider, a local off-air antenna 44, and/or any other desired signal source such as those that locally generate A-V channels (e.g., security camera channels, data networks, or informational channels) using any standard receiving mechanism such as an antenna, modem or cable connection, and places these signals on the cable network 26 for distribution to the IRDs 30-40. These other signals, referred to hereinafter as terrestrial signals, may comprise any cable, satellite or off-air signal including, for example, standard CATV, UHF, VHF, FM radio signals and/or locally generated signals such as security camera or bulletin board channels. The terrestrial signals may be summed or added together in a summing network 46 (which may comprise any standard signal summer) and provided to the transmodulator 20 via a cable line 48, or may be provided separately to the transmodulator 20. The transmodulator 20 may pass the received terrestrial signals to the cable network 26 at the carrier frequencies at which the terrestrial signals are received, or the transmodulator 20 may shift some or all of the terrestrial signals in frequency to use the available frequency spectra of the cable

Asserted Claims	Williams '873
	network 26 more efficiently. Where input terrestrial signals are provided in base-band, suitable RF modulators may be used. Williams '873 at 7:4–23: Preferably, the transmodulator 20 transmodulates selected signals within the two 500 MHz-wide QPSK-modulated downlink signals into 128-QAM-modulated signals, wherein each such transmodulated signal is 6 MHz-wide. The transmodulator 20 may then place each of the transmodulated 6 MHz-wide, 128-QAM-modulated signals on the cable network 26 at any unused or desired carrier frequency bands while, simultaneously, sending the terrestrial signals over the cable network 26 at any other desired carrier frequency bands. Alternatively, the transmodulator 20 may use any other desired modulation technique to remodulate selected ones of the received satellite signals. In fact, in some cases in which only a few of the selected signals are being distributed, the transmodulator may not need to remodulate the selected signals but may, instead, send these signals over the cable network 26 at the received modulation scheme. As noted above, the transmodulator 20 may provide the transmodulated signals and/or the terrestrial signals to the IRDs 30-40 over any wireless network, if so desired. Williams '873 at 7:24–47: Each of the IRDs 30-40 receives the selected ones of the QAM-modulated, 6 MHz-wide signals along with the terrestrial signals from the cable network 26 (or wireless channel) and demodulates a user-selected one of these signals. Each of the IRDs 30-40 then provides the demodulated user-selected signal(s) to an output device or processor, such as a television set (not shown), for display or processing thereby. When a user at one of the IRDs 30-40 requests to receive a particular satellite signal or transmodulator signal, the IRD first checks the current channel assignments to see if the requested signal is available. If so, the IRD demodulates the requested signal and, if not, the IRD sends a request to the transmodulator 20 to tune to, transmodulate and transmit the requested signal over the cable network 26. This request may be sent via the cable network 26, via a different wire network provided in the MDU, via any desired wireless network or via any other

Asserted Claims	Williams '873
	communication channel. If desired, the request signal may be sent to the transmodulator using the well known Multi-Media Cable Network System (MCNS) protocol, which provides communication over the same cable as the video signals. The MCNS protocol typically utilizes the range from 5 to 42 MHz and enables multiple receivers to communicate to the same transmodulator. Williams '873 at 7:48–8:8: Referring now to FIG. 2, representative methods of combining the transmodulated transponder signals along with terrestrial signals on the cable network 26 are illustrated. The left-most column of FIG. 2 illustrates a previously known method of placing QPSK-modulated signals along with terrestrial signals on a cable network. According to this scheme, all existing terrestrial signals (including cable TV signals) are distributed at, for example, VHF and UHF carrier frequencies below 950 MHz while one of the 500 MHz-wide QPSK-modulated signals (associated with either the LHCP or the RHCP component of the satellite signal) is placed directly on the cable network at the unused band between about 950 MHz and 1450 MHz. A major problem with this configuration is that only the RHCP or the LHCP transponder signals can be placed on a 1450 MHz capable cable network at any given time which, in turn, prevents IRDs within an MDU from decoding or receiving channels associated with the other of the LHCP or the RHCP transponder signals. While this problem can be overcome by running two cable lines throughout an MDU or by utilizing a high frequency cable plant capable of approximately 2 GHz or greater bandwidth, these solutions require additional equipment and expense and are not adaptable to most existing cable plants now in use. Furthermore, the signals provided at the 950 MHz to 1450 MHz band can be severely degraded by the cable plant due to the poor high frequency propagation properties of many existing cable plants, especially older cable plants. Williams '873 at 9:28–39: In accordance with the present invention, the number of transmodulator channels is less than the number of transponder signals associated with the received satellite or other signal

Asserted Claims	Williams '873
	and, in a preferred embodiment, the transmodulator 20 includes up to, but less than, 32 transmodulator channels, each of which includes a switch 53, a tuner 54, a satellite decoder 56, a packetizer 58, a cable encoder 60, and an upconverter 62. Each transmodulator channel decodes and transmodulates one of the 32 received transponder signals associated with the downlink signal in essentially the same manner and, as a result, the operation of only one of the transmodulator channels will be described herein. Williams '873 at 9:40–48: The tuner 54 of a transmodulator channel tunes to one of the transponder signals associated with either the RHCP or the LHCP signal within the L-band range between 950 and 1450 MHz provided through the switch 53, while filtering out the other 15 transponder signals within that band, to produce a 24 MHz-wide, QPSK-modulated signal corresponding to a selected one of the 32 satellite transponder signals. If desired, the tuner 54 may shift the tuned 24 MHz-wide, QPSK-modulated signal down to baseband. Williams '873 at 10:24–39: In the configuration of FIG. 3, each of the summers 64 receives an input from, for example, four of the upconverters 62, each of which upconverts to a different one of the four carrier IFs. Each of the summers 64 combines the four received transmodulated signals to produce, for example, one of up to eight groups of four, 6 MHz-wide transmodulated signals. The summers 64 of FIG. 3 provide up to eight such groups of four, 6 MHz-wide signals to a variable frequency upconverter 66 which, in turn, upconverts each of the up to eight groups of four, 6 MHz-wide signals to a different carrier frequency band. A summer 68 then combines these upconverted transmodulated signals with each other and with any desired frequency-shifted or non-frequency-shifted terrestrial signals (delivered by a level shifter 70) for propagation over the cable network 26 of FIG. 1. Williams '873 at 10:53–11:5: A transmodulator control unit 72, which may be implemented in the form of a microprocessor or any other digital or analog controller, preferably controls the switches



Asserted Claims	Williams '873
	53, tuners 54, the satellite decoders 56, the packetizers 58, the cable encoders 60, the upconverters 62, the variable frequency upconverter 66 and the level shifter 70 in any desired manner. To implement such control, however, the control unit 72 receives satellite signal requests from the IRDs 30-40 which are received, demodulated and decoded by a demodulator/decoder 73. These satellite signal requests may be transmitted from the IRDs 30-40 over the cable network 26 at, for example, a dedicated frequency, over some other wire network or via any desired wireless network. The satellite signal requests may be digital or analog requests using any desired or known communication format, such as MCNS. These requests may be sent from the IRDs 30-40 periodically to indicate to the control unit 72 which satellite transponder signals are being actively requested by the IRDs 30-40 or these requests may be sent when an IRD initially tries to tune to one of the satellite transponder signals. Williams '873 at 11:6–21: Generally, the control unit 72 assimilates all of the satellite signal requests received from the IRDs 30-40, determines which of the satellite signals or transponder signals must be decoded to satisfy these requests and controls a different one of the transmodulator channels to transmodulate each of the so-determined transponder signals for transmission over the cable network 26. The control unit 72 may cause the selected transponder signals to be transmodulated by controlling the tuners 54 of different ones of the transmodulator channels to tune to a specific one of the selected transponder signals. Williams '873 at 11:36–67: The control unit 72 may control the frequencies used by the upconverters 62 and 66 and/or the level shifter 70 to control the carrier frequencies at which the transmodulated signals, as well as the terrestrial signals, are transmitted over the cable network 26. In a preferred embodiment, the transmodulator control unit 72 automatically determines which

Asserted Claims	Williams '873
	frequencies to use as carrier frequencies for the selected ones of the 32, 6 MHz-wide transmodulated signals (or other transmodulated signals) developed by each of the transmodulator channels. In this preferred configuration, the transmodulator control unit 72 may include a signal detector (not shown) attached to the line 48 upon which the terrestrial signals are received. At start up or at any other desired time, the signal detector scrolls through or scans the frequency bands between about 54 MHz and 806 MHz (and higher bands if desired) and checks the power lever and/or tries to tune to standard channel locations to determine which channel locations are being used for terrestrial signals. Typically standard terrestrial channel locations are spaced 6 MHz apart. If the signal detector detects enough power and/or is able to tune to a standard channel, e.g., if it tunes to a carrier signal and gets a video sync code, the control unit 72 identifies that the band associated with that channel is being used by a terrestrial (e.g., CATV) signal. However, if the signal detector does not detect sufficient power and/or is unable to tune to any particular channel, the band associated with that channel is identified as an empty band and, therefore, as potentially available for use with one or more of the transmodulated signals. The control unit 72 may, instead, include any standard channel or frequency sniffer which locates the frequency bands used by the received terrestrial signals in any other desired manner. Williams '873 at 12:1–6: After the control unit 72 identifies all of the empty or unused frequency bands, this information is preferably stored in non-volatile memory. Operator selection (e.g., by means of a keypad) may also be utilized to select or de-select frequency bands, either alone or in conjunction with an automated system. Williams '873 at 12:7–16: The control unit 72 may then, in one embodiment, start at the lowest unoccupied band, determine if this band is wide enough to carry one or more, i.e., any desired number, of the transmodulated signals and, if so, identify that band for use by a specific one or more of the transmodulated signals by changing the output frequency of, for example, the

Asserted Claims	Williams '873
	upconverter 66 associated with those transmodulated signals. The control unit 72 may go as high as necessary in frequency to assign carrier frequencies to all of the transmodulated signals. Williams '873 at 12:17–34: If the terrestrial signals are spread out throughout the available cable spectra in a manner which makes it impossible or difficult to find empty bands of sufficient predetermined width for all of the desired transmodulated signals, the control unit 72 and/or operator input may identify one or more of the terrestrial signals and/or the satellite channels to be eliminated (not provided over the system) or shifted in frequency to thereby produce sufficient regions of continuous spectrum for use by any desired subsets or groupings of the transmodulated signals. In the case in which one or more of the terrestrial signals or the satellite signals are eliminated, the control unit 72 preferably selects the one or more signals for elimination based on a predetermined priority criterion which may be, for example, input by a user or stored in a memory associated with the control unit 72. The priority criterion may prioritize the satellite or terrestrial signals for elimination based on the channel or frequency at which these signals arrive at the transmodulator 20 or based on any other desired criteria. Williams '873 at 12:35–47: A transmodulator control panel 74 is coupled to the control unit 72 and, preferably, includes signal strength measurement devices that indicate the relative strength of each of the satellite signals and/or each of the terrestrial signals input to the transmodulator 20. The control panel 74 may also allow an operator to choose default frequency locations for each of the transmodulated and/or terrestrial signals and may include controls that permit an installer to select the carrier frequency bands for any number of the transmodulated and/or terrestrial signals. Of course, the transmodulator control panel 74 and the control unit 72 may perform any other desired functions with respect to the transmodulator 20. Williams '873 at 15:15–27:

Asserted Claims	Williams '873
	Still further, the transmodulator 20 need not remodulate the received transponder signals but may, instead, shift selected ones of these signals to different frequencies for transmission over the cable network 26. In this case, each transmodulator channel would need to include a tuner and a frequency shifter. Of course, this configuration only reduces the bandwidth used by the signals transmitted over the cable network 26 to the extent that it eliminates some of the received satellite transponder signals. Thus, the more received satellite transponder signals that are to be sent to the IRDs 30-40, i.e., the more transmodulator channels there are, the less viable this option becomes. Williams '873 at 15:53–16:4: The IRD 30 may initially scan all the channels from, for example, low carrier frequencies to high carrier frequencies, to locate the frequency bands or channels used by the selected ones of the transmodulated signals and then assign channel numbers to these located signals based on a predetermined ordering scheme used by the transmodulator 20. However, as noted above, the transmodulator 20 may actively signal the channel locations, ordering, frequency assignments, etc. of the transmodulated satellite signals and/or terrestrial signals via a communication channel (using side data) established over, for example, the cable network 26. Such a communication channel may comprise a low-speed channel that uses uncoded bits of the sync and error code bytes within the, for example, 188 byte data packets, and may be used to deliver any desired information to the IRD 30 over time, i.e., using a large number of the 188 byte data packets. Williams '873 at 16:5–21: The IRD 30 includes a controller 105 that receives satellite signal requests from a user and then sends requests to the transmodulator 20 via, for example, an MCNS interface 107 and the cable network 26, to have the requested transponder signals transmodulated and transmitted to the IRD 30 via the cable network 26. The controller 105 also receives and decodes information from the transmodulator 20 indicating the carrier frequencies, etc. of the transmodulated signals that are on the cable network 26. When the controller 105 recognizes that a user-requested channel is being transmodulated and sent via the cable

Asserted Claims	Williams '873
	network 26, the controller 105 controls a tuner 110, connected to the cable network 26, to tune to the frequency band associated with the requested signal. If necessary, the tuner 110 may include a down-converter which shifts higher frequency 6 MHz channels to lower frequencies commonly supported by standard tuners. Williams '873 at 16:22–42: The tuned signal is provided to a decoder 112, which may comprise a standard DVB cable decoder such as the BCM3118 decoder chip manufactured by Broadcom Corp. Generally, the decoder 112 includes a 128-QAM demodulator that demodulates the QAM transmodulated signal to produce a set of interleaved, R-S encoded data packets. A de-interleaver de-interleaves the data packets and, thereafter, an R-S decoder strips off the error coding and, to the extent possible, corrects errors resulting from transmission over the cable, to produce a stream of 188 byte data packets. Thereafter a descrambler descrambles each of the 188-byte data packets to remove the effects of the scrambler 90 of FIG. 6. The DVB cable decoder 112 delivers the stream of 188 byte data packets, each having 187 bytes of data and one sync byte, to a packetizer 114 while, simultaneously, providing an indication of whether the data associated with each of the 188 byte data packets has experienced a non-recoverable error during transmission over the cable network 26. This indication may be developed by the R-S decoder of the DVB decoder 112 and provided to the packetizer 114 via, for example, a line 115. Williams '873 at Fig. 2:

Asserted Claims	Williams '873
	 FIG. 2 To the extent Williams '873 does not explicitly and/or inherently disclose this element, it would have been obvious in view of the knowledge of a person of ordinary skill in the art in light of Williams '873 alone or it would have been obvious to combine Williams '873 with one or more prior art references identified in the cover document to which this chart is attached and/or in Appendix B thereto.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

Receipt is acknowledged of this non-provisional utility patent application. The application will be taken up for examination in due course. Applicant will be notified as to the results of the examination. Any correspondence concerning the application must include the following identification information: the U.S. APPLICATION NUMBER, FILING DATE, NAME OF FIRST INVENTOR, and TITLE OF INVENTION. Fees transmitted by check or draft are subject to collection.

Please verify the accuracy of the data presented on this receipt. If an error is noted on this Filing Receipt, please submit a written request for a corrected Filing Receipt, including a properly marked-up ADS showing the changes with strike-through for deletions and underlining for additions. If you received a "Notice to File Missing Parts" or other Notice requiring a response for this application, please submit any request for correction to this Filing Receipt with your reply to the Notice. When the USPTO processes the reply to the Notice, the USPTO will generate another Filing Receipt incorporating the requested corrections provided that the request is grantable.

PROTECTING YOUR INVENTION OUTSIDE THE UNITED STATES

Since the rights granted by a U.S. patent extend only throughout the territory of the United States and have no effect in a foreign country, an inventor who wishes patent protection in another country must apply for a patent in a specific country or in regional patent offices. Applicants may wish to consider the filing of an international application under the Patent Cooperation Treaty (PCT). An international (PCT) application generally has the same effect as a regular national patent application in each PCT-member country. The PCT process **simplifies** the filing of patent applications on the same invention in member countries, but **does not result** in a grant of "an international patent" and does not eliminate the need of applicants to file additional documents and fees in countries where patent protection is desired.

Almost every country has its own patent law, and a person desiring a patent in a particular country must make an application for patent in that country in accordance with its particular laws. Since the laws of many countries differ in various respects from the patent law of the United States, applicants are advised to seek guidance from specific foreign countries to ensure that patent rights are not lost prematurely.

Applicants also are advised that in the case of inventions made in the United States, the Director of the USPTO must issue a license before applicants can apply for a patent in a foreign country. The filing of a U.S. patent application serves as a request for a foreign filing license. The application's filing receipt contains further information and guidance as to the status of applicant's license for foreign filing.

Applicants may wish to consult the USPTO booklet, "General Information Concerning Patents" (specifically, the section entitled "Treaties and Foreign Patents") for more information on timeframes and deadlines for filing foreign

patent applications. The guide is available either by contacting the USPTO Contact Center at 800-786-9199, or it can be viewed on the USPTO website at http://www.uspto.gov/web/offices/pac/doc/general/index.html.

For information on preventing theft of your intellectual property (patents, trademarks and copyrights), you may wish to consult the U.S. Government website, http://www.stopfakes.gov. Part of a Department of Commerce initiative, this website includes self-help "toolkits" giving innovators guidance on how to protect intellectual property in specific countries such as China, Korea and Mexico. For questions regarding patent enforcement issues, applicants may call the U.S. Government hotline at 1-866-999-HALT (1-866-999-4258).

LICENSE FOR FOREIGN FILING UNDER

Title 35, United States Code, Section 184

Title 37, Code of Federal Regulations, 5.11 & 5.15

GRANTED

The applicant has been granted a license under 35 U.S.C. 184, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" followed by a date appears on this form. Such licenses are issued in all applications where the conditions for issuance of a license have been met, regardless of whether or not a license may be required as set forth in 37 CFR 5.15. The scope and limitations of this license are set forth in 37 CFR 5.15(a) unless an earlier license has been issued under 37 CFR 5.15(b). The license is subject to revocation upon written notification. The date indicated is the effective date of the license, unless an earlier license of similar scope has been granted under 37 CFR 5.13 or 5.14.

This license is to be retained by the licensee and may be used at any time on or after the effective date thereof unless it is revoked. This license is automatically transferred to any related applications(s) filed under 37 CFR 1.53(d). This license is not retroactive.

The grant of a license does not in any way lessen the responsibility of a licensee for the security of the subject matter as imposed by any Government contract or the provisions of existing laws relating to espionage and the national security or the export of technical data. Licensees should apprise themselves of current regulations especially with respect to certain countries, of other agencies, particularly the Office of Defense Trade Controls, Department of State (with respect to Arms, Munitions and Implements of War (22 CFR 121-128)); the Bureau of Industry and Security, Department of Commerce (15 CFR parts 730-774); the Office of Foreign AssetsControl, Department of Treasury (31 CFR Parts 500+) and the Department of Energy.

NOT GRANTED

No license under 35 U.S.C. 184 has been granted at this time, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" DOES NOT appear on this form. Applicant may still petition for a license under 37 CFR 5.12, if a license is desired before the expiration of 6 months from the filing date of the application. If 6 months has lapsed from the filing date of this application and the licensee has not received any indication of a secrecy order under 35 U.S.C. 181, the licensee may foreign file the application pursuant to 37 CFR 5.15(b).

SelectUSA

The United States represents the largest, most dynamic marketplace in the world and is an unparalleled location for business investment, innovation, and commercialization of new technologies. The U.S. offers tremendous resources and advantages for those who invest and manufacture goods here. Through SelectUSA, our nation works to promote and facilitate business investment. SelectUSA provides information assistance to the international investor community; serves as an ombudsman for existing and potential investors; advocates on behalf of U.S. cities, states, and regions competing for global investment; and counsels U.S. economic development organizations on investment attraction best practices. To learn more about why the United States is the best country in the world to develop technology, manufacture products, deliver services, and grow your business, visit http://www.SelectUSA.gov or call +1-202-482-6800.

EXHIBITS AND APPENDICES

Exhibits A1 – A15	Invalidity Claim Charts for Primary References for ’576 Patent
Exhibits B1 – B13	Invalidity Claim Charts for Primary References for ’715 Patent
Exhibits C1 – C14	Invalidity Claim Charts for Primary References for ’008 Patent
Appendix A	Additional References and Obviousness Chart for ’576 Patent
Appendix B	Additional References and Obviousness Chart for ’715 Patent
Appendix C	Additional References and Obviousness Chart for ’008 Patent

Pursuant to P.R. 3-3 and the Court's Docket Control Order (Dkt. 49), Defendants DISH Network Corporation, DISH Network L.L.C., and DISH Network Service L.L.C. (collectively, "Defendants") hereby provide these P.R. 3-3 Invalidity Contentions ("Invalidity Contentions") to Plaintiff Entropic Communications, LLC ("Plaintiff" or "Entropic").

I. INTRODUCTORY STATEMENT

These Invalidity Contentions are based on Defendants' current knowledge and understanding of U.S. Patent Nos. 7,130,576 ("the '576 patent"); 7,542,715 ("the '715 patent"); and 8,792,008 ("the '008 patent") (collectively, "the Asserted Patents") and the prior art, along with Defendants' understanding of Plaintiff's infringement allegations and apparent claim interpretations based on those allegations, as set forth in Plaintiff's Disclosure of Asserted Claims and Infringement Contentions ("Infringement Contentions"). These Invalidity Contentions should not be construed to waive any objections to Plaintiff's Infringement Contentions or as an admission that the Infringement Contentions were adequate or that Plaintiff's apparent claim interpretations are correct, have merit, or should be adopted. Indeed, Plaintiff's Infringement Contentions are deficient and fail to describe the accused functionality and Plaintiff's interpretation of the claim language in a manner that would allow Defendants to fully respond, including in these invalidity contentions. Defendants expressly reserve the right to amend these contentions based on amendments to Plaintiff's Infringement Contentions or when Plaintiff specifies its theories with greater clarity. Additionally, and as further explained below, where these Invalidity Contentions disclose that a prior art reference meets a claim limitation, such position may be based on Plaintiff's apparent claim interpretations in its Infringement Contentions; Defendants do not necessarily agree that such interpretations are correct, have merit, or should be adopted.

Defendants' investigation of the Asserted Patents, their file histories, and the prior art is ongoing, and Defendants expressly reserve the right to supplement these Invalidity Contentions

based on further discovery and in a manner consistent with the Federal Rules of Civil Procedure, the Local Patent Rules for the Eastern District of Texas, and any Docket Control Order, or otherwise in accordance with any order or direction of this Court or agreement of the parties. Defendants' ongoing investigation includes, but is not limited to, serving subpoenas on prior artists and inventors regarding prior art, seeking additional information related to the references and prior art systems disclosed in these Invalidity Contentions, seeking additional information regarding Plaintiff's Infringement Contentions and the products and services accused of infringement, and seeking information regarding any prior sales and/or uses by the original assignees of the Asserted Patents. Defendants also reserve the right to rely on any prior art identified or disclosed by non-parties to this action that are involved in a suit or action involving one or more of the Asserted Patents, as well as any prior art produced or disclosed by Entropic during the course of this litigation. Additionally, Defendants have not yet had the benefit of taking the depositions of the named inventors or those that worked with the named inventors, or of the named inventors, authors, and entities listed on any references or systems identified in these Invalidity Contentions.

II. ASSERTED PATENTS AND CLAIMS

Plaintiff asserts the following claims from the Asserted Patents (collectively, "the Asserted Claims"):

Asserted Patent	Asserted Claims
'576 patent	14–23, 34–42
'715 patent	9–12
'008 patent	1–5, 7, 9–13, 15, 17, 18

Plaintiff asserts a priority date for the '576 and '715 patents of November 7, 2001, and for the '008 patent of September 8, 2011. Reference to an "asserted priority date" should not be construed to mean that Defendants agree that the Asserted Patents are in fact entitled to such priority dates, or that Plaintiff has provided proper notice as to its contentions for priority dates.

P.R. 3-2(b) requires Plaintiff to produce, contemporaneously with its Disclosure of Asserted Claims and Infringement Contentions," "[a]ll documents evidencing the conception, reduction to practice, design, and development of each claimed invention, which were created on or before the date of application for the patent in suit or the priority date identified pursuant to P.R. 3-1(e), whichever is earlier." Plaintiff did not produce any documents pursuant to P.R. 3-2(b). Defendants thus understand that Plaintiff is not asserting an invention date, or conception, reduction to practice, design, and/or development of the claimed invention, prior to the asserted priority dates identified above. To the extent Plaintiff later properly alleges that any such activities occurred prior to the priority dates identified above, Defendants reserve the right to object to such belated changes in position and/or to supplement these Invalidity Contentions to address any such contention, including by identifying and/or charting additional prior art that may become relevant in view of such assertion. Likewise, to the extent Plaintiff successfully establishes an invention date before any of the prior-art references relied on by Defendants, then those references serve as evidence of secondary considerations of obviousness, particularly, contemporaneous invention by others. To the extent Plaintiff alleges that any prior art relied on in these Invalidity Contentions does not actually qualify as prior art to the Asserted Patent, Defendants reserve the right to rebut those allegations (*e.g.*, by demonstrating an earlier critical date for the challenged prior art and/or a later priority date and/or date of invention for a particular Asserted Claim). Defendants also reserve the right to rely on additional documents, information, and evidence to demonstrate public availability or public availability by a certain date of a prior art reference or to rebut any efforts by Plaintiff to allege any reference was not publicly available or publicly available by a certain date or otherwise available as prior art.

For purposes of these contentions, Defendants address only those claims specifically asserted by Plaintiff. Defendants reserve the right to amend or supplement this disclosure as

necessary in view of any changes or amendments made, for any reason, to Plaintiff's infringement theories, infringement contentions, or Asserted Claims, including to Plaintiff's asserted priority and/or invention date(s).

III. CLAIM CONSTRUCTION

To the extent that these Invalidity Contentions rely on or otherwise embody particular constructions of terms or phrases in the Asserted Claims, Defendants are not conceding that any such constructions are proper. For purposes of these Invalidity Contentions, Defendants may adopt alternative claim construction positions. In particular, portions of these Invalidity Contentions, including the claim charts attached as exhibits, may be based on the underlying claim constructions and/or interpretations in Plaintiff's Infringement Contentions, to the extent such constructions and/or interpretations are understood by Defendants. Defendants do not concede that any such constructions or interpretations by Plaintiff are proper, and expressly reserve the right to contest any such constructions.

Throughout the attached Exhibits, Defendants provide examples of where references disclose subject matter recited in preambles, without regard to whether the preambles are properly considered to be limitations of the Asserted Claims. Defendants reserve the right to argue, at the appropriate stage of this case, that the preambles are or are not limitations. Further, the fact that Defendants provide examples of any limitation does not mean that Defendants believe that the limitation is defined, or otherwise enabled, or comports with the requirements of the patent statute, including, but not limited to, 35 U.S.C. § 112.

Nothing disclosed herein is an admission or acknowledgement that any of Defendants' products or services infringes any of the Asserted Claims. Defendants reserve the right to supplement, modify, or otherwise amend these Invalidity Contentions, including based on the Court's claim construction rulings or opinions or the parties' positions or arguments taken in

connection with the claim construction process. Moreover, Defendants reserve the right to rely on any disclosures in the accompanying P.R. 3-4(b) production as it believes necessary in view of positions Plaintiff may take with respect to the scope and meaning of the Asserted Claims.

IV. P.R. 3-3(a) – IDENTIFICATION OF PRIOR ART[1]

A. '576 Patent

3. Prior Art Sales/Public Uses

Item Offered for Sale and/or Publicly Used or Known	Date of Offer / Public Use / Knowledge[8]	Person or Entity Who Made and Received Offer, Made Public Use, or Made Information Known or to Whom Made Known
Full Band Capture Chip BCM3124/BCM3128	On or before June 13, 2011	Broadcom to general public
Full Band Capture Chip BCM4528	On or before September 5, 2011	Broadcom to general public
Super Buddy Satellite Meter	On or before December 2009	Applied Instruments, Inc. to general public

V. PRIMARY REFERENCES

The primary prior art references that Defendants rely on for the Asserted Patents are identified below. The exhibits to these Invalidity Contentions contain claim charts for the primary prior art references. Obviousness combinations of the primary prior art references are separately identified throughout these Invalidity Contentions (including below and in Appendices A–C).

[8] The dates in this column are the latest dates on which the systems were publicly used or known. Defendants reserve the right to identify earlier dates should such dates be ascertained through discovery.

Defendants' reliance on each prior art reference identified throughout these Invalidity Contentions (whether primary references or obviousness references) includes the reference itself, anything incorporated by the reference, any system embodying the reference, and any testimony by those with knowledge of the reference, such as named authors and inventors.[9] All such documents and information shall be considered one prior art reference to the extent they describe a single prior art system or solution, or the closely related work of a single prior art author. In addition to the specific references below, Defendants reserve the right to rely on all admitted prior art in the Asserted Patents and their file histories, as well as anything admitted by prior art by Plaintiff or its experts or representatives. Defendants reserve the right to supplement these Invalidity Contentions as discovery reveals further information about prior use and/or prior public knowledge of products, methods, or systems that Defendants have reason to believe anticipate or render obvious one or more of the Asserted Claims. Defendants further reserve the right to identify and rely on additional prior art in Plaintiff's possession, custody, or control that has not yet been produced or identified to Defendants.

A. '576 Patent

The following primary references, alone or in combination with any other reference identified in this subsection or the references identified in Appendix A, render invalid one or more of the Asserted Claims of the '576 patent.

1. International Patent Publication No. WO 00/03542 ("Ardemagni")

Ardemagni was filed on June 18, 1999, and published on January 20, 2000. Ardemagni qualifies as prior art to the '576 patent under at least 35 U.S.C. §§ 102(a) and/or (b). Ardemagni

[9] For example, for each patent identified as a prior art reference in these Invalidity Contentions, Defendants reserve the right to rely on the patent itself and/or any system that practices or embodies the patent to demonstrate invalidity.

anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A1 provides representative, non-limiting examples of where Ardemagni discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Ardemagni does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Ardemagni alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Ardemagni with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

2. U.S. Patent No. 6,745,392 ("Basawapatna")

Basawapatna was filed on September 8, 1999, and issued on June 1, 2004. Basawapatna qualifies as prior art to the '576 patent under at least 35 U.S.C. §§ 102(a) and (e). Basawapatna anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A2 provides representative, non-limiting examples of where Basawapatna discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Basawapatna does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Basawapatna alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Basawapatna with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

3. European Patent Application EP 0 740 434 ("Carnero")

Carnero published on October 30, 1997. Carnero qualifies as prior art to the '576 patent under at least 35 U.S.C. §§ 102(a) and (b). Carnero anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A3 provides representative, non-limiting examples of where Carnero discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Carnero does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Carnero alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Carnero with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

4. U.S. Patent Publication No. 2002/0154,055 ("Davis '055")

Davis '055 published on October 24, 2002, and claims priority to U.S. Provisional Patent App. No. 28/459301, which was filed on April 18, 2001. Davis '055 qualifies as prior art to the '576 patent under at least 35 U.S.C. § 102(e). Davis '055 anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A4 provides representative, non-limiting examples of where Davis '055 discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Davis '055 does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Davis '055 alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Davis '055 with concepts from other prior art, including any of the other primary references

or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

5. U.S. Patent No. 6,600,730 ("Davis '730")

Davis '730 was filed on August 20, 1998, and issued on July 29, 2003. Davis '730 qualifies as prior art to the '576 patent under at least 35 U.S.C. § 102(e). Davis '730 anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A5 provides representative, non-limiting examples of where Davis '730 discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Davis '730 does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Davis '730 alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Davis '730 with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

6. International Patent Publication No. WO 00/67401 ("Gregoire")

Gregoire was filed as PCT No. US00/12401 on May 4, 2000, and published on November 9, 2000. Gregoire qualifies as prior art to the '576 patent under at least 35 U.S.C. §§ 102(a) and/or (e). Gregoire anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A6 provides representative, non-limiting examples of where Gregoire discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Gregoire does not anticipate any Asserted Claim, such Asserted Claim would be

obvious in view of Gregoire alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Gregoire with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

7. European Patent Application EP 1 071 286 ("Inose")

Inose published on July 20, 2000. Inose qualifies as prior art to the '576 patent under at least 35 U.S.C. §§ 102(a) and (b). Inose anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A7 provides representative, non-limiting examples of where Inose discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Inose does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Inose alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Inose with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

8. U.S. Patent No. 7,954,127 ("James")

James was filed on September 25, 2002, and issued on May 31, 2011. James qualifies as prior art to the '576 patent under at least 35 U.S.C. § 102(e). James anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A8 provides representative, non-limiting examples of where James discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that James does not anticipate any

Asserted Claim, such Asserted Claim would be obvious in view of James alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify James with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

9. Korean Patent Application No. 0142730 ("Kang")

Kang published on November 25, 1996. Kang qualifies as prior art to the '576 patent under at least 35 U.S.C. §§ 102(a) and (b). Kang anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A9 provides representative, non-limiting examples of where Kang discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Kang does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Kang alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Kang with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

10. U.S. Patent No. 6,697,603 ("Lovinggood")

Lovinggood was filed on December 19, 1999, and issued on February 24, 2004. Lovinggood qualifies as prior art to the '576 patent under at least 35 U.S.C. § 102(e). Lovinggood anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A10 provides representative, non-limiting examples of where Lovinggood discloses, either expressly

or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Lovinggood does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Lovinggood alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Lovinggood with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

11. U.S. Patent No. 5,276,904 ("Mutzig")

Mutzig issued on January 4, 1994. Mutzig qualifies as prior art to the '576 patent under at least 35 U.S.C. §§ 102(a), (b) and/or (e). Mutzig anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A11 provides representative, non-limiting examples of where Mutzig discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Mutzig does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Mutzig alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Mutzig with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

12. U.S. Patent No. 5,959,592 ("Petruzzelli")

Petruzzelli issued on September 29, 1999. Petruzzelli qualifies as prior art to the '576 patent under at least 35 U.S.C. §§ 102(a), (b) and/or (e). Petruzzelli anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted

Claims of the '576 patent. The claim chart attached as Exhibit A12 provides representative, non-limiting examples of where Petruzzelli discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Petruzzelli does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Petruzzelli alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Petruzzelli with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

13. U.S. Patent Publication No. 2003/0165200 ("Pugel '200")

Pugel '200 was filed on August 30, 2001, and published on September 4, 2003. Pugel '200 qualifies as prior art to the '576 patent under at least 35 U.S.C. § 102(e). Pugel '200 anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A13 provides representative, non-limiting examples of where Pugel '200 discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Pugel '200 does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Pugel '200 alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Pugel '200 with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

14. U.S. Patent No. 6,134,419 ("Williams '419")

Williams '419 issued on October 17, 2000. Williams '419 qualifies as prior art to the '576 patent under at least 35 U.S.C. §§ 102(a), (b) and/or (e). Williams '419 anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '576 patent. The claim chart attached as Exhibit A14 provides representative, non-limiting examples of where Williams '419 discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Williams '419 does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Williams '419 alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Williams '419 with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

15. U.S. Patent No. 6,493,873 ("Williams '873")

Williams '873 was filed on January 20, 1998, and issued on December 10, 2002. Williams '873 qualifies as prior art to the '576 patent under at least 35 U.S.C. § 102(e). Williams '873 anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '873 patent. The claim chart attached as Exhibit A15 provides representative, non-limiting examples of where Williams '873 discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Williams '873 does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Williams '873 alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Williams '873 with concepts from other prior art, including any of the other primary references or the references identified in Appendix A

or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

B. '715 Patent

The following primary references, alone or in combination with any other reference identified in this subsection or the references identified in Appendix A, render invalid one or more of the Asserted Claims of the '715 patent.

1. International Patent Publication No. WO 00/03542 ("Ardemagni")

Ardemagni was filed on June 18, 1999, and published on January 20, 2000. Ardemagni qualifies as prior art to the '715 patent under at least 35 U.S.C. §§ 102(a) and/or (b). Ardemagni anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B1 provides representative, non-limiting examples of where Ardemagni discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Ardemagni does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Ardemagni alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Ardemagni with concepts from other prior art, including any of the other primary references or the references identified in Appendix B or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

2. European Patent Application EP 0 740 434 ("Carnero")

Carnero published on October 30, 1997. Carnero qualifies as prior art to the '715 patent under at least 35 U.S.C. §§ 102(a) and (b). Carnero anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B2 provides representative, non-limiting

examples of where Carnero discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Carnero does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Carnero alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Carnero with concepts from other prior art, including any of the other primary references or the references identified in Appendix B or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

3. U.S. Patent Publication No. 2002/0154,055 ("Davis '055")

Davis '055 published on October 24, 2002, and claims priority to U.S. Provisional Patent App. No. 28/459301, which was filed on April 18, 2001. Davis '055 qualifies as prior art to the '715 patent under at least 35 U.S.C. § 102(e). Davis '055 anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B3 provides representative, non-limiting examples of where Davis '055 discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Davis '055 does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Davis '055 alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Davis '055 with concepts from other prior art, including any of the other primary references or the references identified in Appendix B or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

4. U.S. Patent No. 6,600,730 ("Davis '730")

Davis '730 was filed on August 20, 1998, and issued on July 29, 2003. Davis '730 qualifies as prior art to the '715 patent under at least 35 U.S.C. § 102(e). Davis '730 anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B4 provides representative, non-limiting examples of where Davis '730 discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Davis '730 does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Davis '730 alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Davis '730 with concepts from other prior art, including any of the other primary references or the references identified in Appendix B or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

5. International Patent Publication No. WO 02/065771 ("Fisk")

Fisk has an international filing date of February 9, 2001, and published on August 22, 2002. Fisk published in the English language and designates the United States. Fisk qualifies as prior art to the '715 patent under at least 35 U.S.C. § 102(e). Fisk anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B5 provides representative, non-limiting examples of where Fisk discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Fisk does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Fisk alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Fisk with concepts from other prior art, including any of the other primary references or the

references identified in Appendix B or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

6. International Patent Publication No. WO 00/67401 ("Gregoire")

Gregoire was filed as PCT No. US00/12401 on May 4, 2000, and published on November 9, 2000. Gregoire qualifies as prior art to the '715 patent under at least 35 U.S.C. §§ 102(a) and/or (e). Gregoire anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B6 provides representative, non-limiting examples of where Gregoire discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Gregoire does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Gregoire alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Gregoire with concepts from other prior art, including any of the other primary references or the references identified in Appendix B or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

7. U.S. Patent No. 8,601,519 ("Hicks")

Hicks was filed on December 28, 2000, and issued on December 3, 2013. Hicks qualifies as prior art to the '715 patent under at least 35 U.S.C. § 102(e). Hicks anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B7 provides representative, non-limiting examples of where Hicks discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Hicks does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Hicks alone and/or in view of the

knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Hicks with concepts from other prior art, including any of the other primary references or the references identified in Appendix B or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

8. Korean Patent Application No. 0142730 ("Kang")

Kang published on November 25, 1996. Kang qualifies as prior art to the '715 patent under at least 35 U.S.C. §§ 102(a) and (b). Kang anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B8 provides representative, non-limiting examples of where Kang discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Kang does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Kang alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Kang with concepts from other prior art, including any of the other primary references or the references identified in Appendix B or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

9. U.S. Patent No. 5,276,904 ("Mutzig")

Mutzig issued on January 4, 1994. Mutzig qualifies as prior art to the '715 patent under at least 35 U.S.C. §§ 102(a), (b) and/or (e). Mutzig anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B9 provides representative, non-limiting examples of where Mutzig discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Mutzig does not anticipate any

Asserted Claim, such Asserted Claim would be obvious in view of Mutzig alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Mutzig with concepts from other prior art, including any of the other primary references or the references identified in Appendix B or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

10. U.S. Patent No. 7,263,713 ("Oishi")

Oishi was filed on February 26, 2001, and issued on May 9, 2002. Oishi qualifies as prior art to the '715 patent under at least 35 U.S.C. § 102(e). Oishi anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B10 provides representative, non-limiting examples of where Oishi discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Oishi does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Oishi alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Oishi with concepts from other prior art, including any of the other primary references or the references identified in Appendix B or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

11. U.S. Patent No. 5,959,592 ("Petruzzelli")

Petruzzelli issued on September 28, 1999. Petruzzelli qualifies as prior art to the '715 patent under at least 35 U.S.C. §§ 102(a), (b) and/or (e). Petruzzelli anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B11 provides representative, non-

limiting examples of where Petruzzelli discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Petruzzelli does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Petruzzelli alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Petruzzelli with concepts from other prior art, including any of the other primary references or the references identified in Appendix B or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

12. U.S. Patent No. 6,134,419 ("Williams '419")

Williams '419 issued on October 17, 2000. Williams '419 qualifies as prior art to the '576 patent under at least 35 U.S.C. §§ 102(a), (b) and/or (e). Williams '419 anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B12 provides representative, non-limiting examples of where Williams '419 discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Williams '419 does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Williams '419 alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Williams '419 with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

13. U.S. Patent No. 6,493,873 ("Williams '873")

Williams '873 was filed on January 20, 1998, and issued on December 10, 2002. Williams '873 qualifies as prior art to the '715 patent under at least 35 U.S.C. § 102(e). Williams '873

anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '715 patent. The claim chart attached as Exhibit B13 provides representative, non-limiting examples of where Williams '873 discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Williams '873 does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Williams '873 alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Williams '873 with concepts from other prior art, including any of the other primary references or the references identified in Appendix A or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

C. '008 Patent

The following primary references, alone or in combination with any other reference identified in this subsection or the references identified in Appendix A, render invalid one or more of the Asserted Claims of the '008 patent.

1. U.S. Patent Publication No. 2007/0286311 ("Coyne")

Coyne was filed on May 1, 2007, and published on December 13, 2007. Coyne qualifies as prior art to the '008 patent under at least 35 U.S.C. §§ 102(a) and 102(b). Coyne anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C1 provides representative, non-limiting examples of where Coyne discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Coyne does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Coyne alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Coyne with concepts from other prior art, including any of the other primary

references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

2. U.S. Patent No. 5,808,671 ("Maycock")

Maycock issued on September 15, 1998. Maycock qualifies as prior art to the '008 patent under at least 35 U.S.C. §§ 102(a) and 102(b). Maycock anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C2 provides representative, non-limiting examples of where Maycock discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Maycock does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Maycock alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Maycock with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

3. U.S. Patent No. 7,403,486 ("Flask")

Flask was filed on November 1, 2004, and issued on July 22, 2008. Flask qualifies as prior art to the '008 patent under at least 35 U.S.C. §§ 102(a) and 102(b). Flask anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C3 provides representative, non-limiting examples of where Flask discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Flask does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Flask alone

and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Flask with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

4. U.S. Patent No. 5,874,992 ("Caporizzo")

Caporizzo was filed on August 16, 1996, and issued on February 23, 1999. Caporizzo qualifies as prior art to the '008 patent under at least 35 U.S.C. §§ 102(a) and 102(b). Caporizzo anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C4 provides representative, non-limiting examples of where Caporizzo discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Caporizzo does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Caporizzo alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Caporizzo with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

5. U.S. Patent No. 8,582,694 ("Velazquez")

Velazquez was filed on April 24, 2012, issued on November 12, 2013, and claims priority to applications filed on October 20, 2010, June 16, 2010, and April 20, 2008. Velazquez qualifies as prior art to the '008 patent under at least 35 U.S.C. §§ 102(a) and 102(e). Velazquez anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C5 provides

representative, non-limiting examples of where Velazquez discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Velazquez does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Velazquez alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Velazquez with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

6. U.S. Patent 7,788,684 ("Petrovic")

Petrovic issued on August 31, 2010. Petrovic qualifies as prior art to the '008 patent under at least 35 U.S.C. §§ 102(a) and 102(b). Petrovic anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C6 provides representative, non-limiting examples of where Petrovic discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Petrovic does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Petrovic alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Petrovic with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

7. Broadcom Full Band Capture Chip System

Broadcom's BCM3128 and BCM3124 full band capture cable chips were announced, publicly known and used, and available for sale on or before June 13, 2011, specifically in set-top

boxes (STBs) and gateways with DOCSIS 3.0, and/or the BCM3128/3128 chips were specifically disclosed as being used in in systems with DOCSIS 3.0. This Full Band Capture Chip System qualifies as prior art to the '008 patent under at least 35 U.S.C. §§ 102(a) and 102(b). Additionally, Broadcom's BCM4528 full band capture satellite chip was announced, publicly known, and used, and available for sale on or before September 6, 2011. The Full Band Capture Chip System anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C7 provides representative, non-limiting examples of where the Full Band Capture Chip System discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that the Full Band Capture Chip System does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of the Full Band Capture Chip System alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify the Full Band Capture Chip System with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

8. U.S. Patent No. 8,126,044 ("Cavanagh")

Cavanagh was filed on October 25, 2006, and issued on February 28, 2012. Cavanagh qualifies as prior art to the '008 patent under at least 35 U.S.C. §§ 102(a) and 102(e). Cavanagh anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C8 provides representative, non-limiting examples of where Cavanagh discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Cavanagh does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view

of Cavanagh alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Cavanagh with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

9. International Telecommunications Union ("ITU")

ITU refers to at least the following documents from the International Telecommunications Union:

- ITU Handbook on Spectrum Monitoring (2011)
- ITU Handbook on Satellite Communications (3d ed. 2002)
- Rec. ITU-R BO.1294 (1997)
- Rec. ITU-R BO.1516 (2001)
- Rec. ITU-R S.1878 (2010)

These documents were publicly available prior to 2012. ITU qualifies as prior art to the '008 patent under at least 35 U.S.C. § 102(a) and/or (b). ITU anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C9 provides representative, non-limiting examples of where ITU discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that ITU does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of ITU alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify ITU with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

10. Digital Video Broadband ("DVB")

DVB refers to at least the following documents related to Digital Video Broadband from the European Telecommunications Standards Institute:

- ETSI EN 301 790 V1.5.1 (Digital Video Broadcasting (DVB); Interaction channel for satellite distribution systems) (May 2009);
- ETSI EN 302 307 V1.2.1 (Digital Video Broadcasting (DVB); Second generation framing structure, channel coding and modulation systems for Broadcasting, Interactive Services, News Gathering and other broadband satellite applications) (April 2009);
- ETSI ER 101 790 V1.4.1 (Digital Video Broadcasting (DVB); Interaction channel for Satellite Distribution Systems; Guidelines for the use of EN 301 790) (July 2009);
- ETSI TR 102 376 V1.1.1 (Digital Video Broadcasting (DVB) User guidelines for the second generation system for Broadcasting, Interactive Services, News Gathering and other broadband satellite applications (DVB-S2)) (February 2005);
- ETSI TR 101 290 V1.2.1 (Digital Video Broadcasting (DVB); Measurement guidelines for DVB systems) (May 2001);
- Digital Satellite Equipment Control (DiSEqC) Specifications (1998), including, *e.g.*, Bus Functional Specification (February 1998); and
- Morello et al., *DVB-S2: The Second Generation Standard for Satellite Broad-band Services* (IEEE January 2006).

These documents were publicly available prior to 2011. DVB qualifies as prior art to the '008 patent under at least 35 U.S.C. § 102(a) and/or (b). DVB anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C10 provides representative, non-limiting examples of where DVB discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that DVB does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of DVB alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify DVB with concepts from other prior art, including any of the other primary references or the

references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

11. U.S. Patent No. 9,686,594 ("Gomez")

Gomez was filed on March 30, 2012, and issued on June 20, 2017. Gomez qualifies as prior art to the '008 patent under at least 35 U.S.C. § 102(e) Gomez anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C11 provides representative, non-limiting examples of where Gomez discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Gomez does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Gomez alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Gomez with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

12. U.S. Patent No. 8,948,316 ("Currivan")

Currivan was filed on March 23, 2012, issued on February 3, 2014, and claims priority to a Provisional Application No. 61/467,659 filed on March 25, 2011. Currivan qualifies as prior art to the '008 patent under at least 35 U.S.C. § 102(e). Currivan anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C12 provides representative, non-limiting examples of where Cavanagh discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Currivan does not anticipate any

Asserted Claim, such Asserted Claim would be obvious in view of Currivan alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Currivan with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

13. U.S. Patent No. 8,175,191 ("Tang")

Tang was filed on February 20, 2008, and issued on May 8, 2012. Tang qualifies as prior art to the '008 patent under at least 35 U.S.C. §§ 102(a) and 102(e). Tang anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted Claims of the '008 patent. The claim chart attached as Exhibit C13 provides representative, non-limiting examples of where Tang discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Tang does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Tang alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Tang with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

14. U.S. Patent No. 8,649,421 ("Renken")

Renken was filed on February 17, 2012, issued on February 11, 2014, and claims priority to a provisional application filed on February 18, 2011. Renken qualifies as prior art to the '008 patent under at least 35 U.S.C. §§102(a) and 102(e). Renken anticipates and/or renders obvious (in combination with the knowledge of a person of ordinary skill in the art) all Asserted

Claims of the '008 patent. The claim chart attached as Exhibit C14 provides representative, non-limiting examples of where Renken discloses, either expressly or inherently, each element, thereby anticipating those claims. To the extent Plaintiff asserts that Renken does not anticipate any Asserted Claim, such Asserted Claim would be obvious in view of Renken alone and/or in view of the knowledge of one of ordinary skill in the art, and it would have been obvious to combine or modify Renken with concepts from other prior art, including any of the other primary references or the references identified in Appendix C or Section VI (State of the Art and Obviousness), and/or in view of the knowledge of one of ordinary skill in the art, including as explained herein, to achieve the claimed inventions.

VI. STATE OF THE ART AND OBVIOUSNESS

The primary references identified above, as further described in the Exhibits, each discloses, either expressly or inherently, every element of the Asserted Claims of the identified Asserted Patent, thereby anticipating those claims. Additionally, each of the primary references alone (including in combination with the knowledge of a person of ordinary skill in the art) renders obvious such Asserted Claims. To the extent Plaintiff contends that any primary reference does not anticipate or render obvious the Asserted Claims as set forth above, it would have been obvious to combine or modify the primary references with concepts from other prior art, as explained throughout these Invalidity Contentions. In particular, for each limitation of the Asserted Claims that Plaintiff contends is not met by a particular primary reference, Defendants contend that the limitation (and claim as a whole) is obvious based on a combination of that particular primary reference with (1) any other primary reference disclosing that limitation, (2) any reference identified in Appendices A–C as disclosing that limitation, (3) any statements made in the intrinsic record of such Asserted Patent, and/or (4) the knowledge of one of ordinary skill in the art (as explained in additional detail below).

Defendants do not yet have the benefit of Plaintiff's positions regarding the prior art, including what element(s), if any, Plaintiff contends are not disclosed by each prior art reference, whether Plaintiff contends that a reference is not in fact prior art, and whether Plaintiff contends that a person of ordinary skill in the art would not be motivated to combine specific references. Defendants reserve the right to supplement these obviousness positions (including identifying additional prior art combinations and the associated reasons to combine) in view of such positions and/or as discovery in the case, including expert discovery, progresses.

The information discussed in the prior art raised in these Invalidity Contentions (including all referenced listed in the P.R. 3-3(a) – Identification of Prior Art) forms part of the background knowledge of a person of ordinary skill in the art at the time each of the Asserted Patents was filed and would have been used in determining whether and how to combine references to achieve the claimed invention(s), as discussed herein.[10] Indeed, the existence, nature, and content of each prior art reference, including the prior art references cited here, provide further evidence regarding the knowledge of a person of ordinary skill in the art at the relevant time. Defendants expressly reserve the right to rely on each of the prior art references, systems, concepts, and technologies discussed in these Invalidity Contentions, including to demonstrate that a particular claim element was known at the time of the Asserted Patents to a person of ordinary skill in the art, to show that the differences between a claimed invention and a prior art reference would have been obvious to a person of ordinary skill in the art, and to establish that a person of ordinary skill in the art would have been motivated to combine teachings of one or more references to achieve a claimed invention.

[10] *See Randall Mfg. v. Rea*, 733 F.3d 1355, 1362 (Fed. Cir. 2013) (stating that "the knowledge [of a person of ordinary skill in the art] is part of the store of public knowledge that must be consulted when considering whether a claimed invention would have been obvious").

A. General Motivations for Making Combinations of Prior Art

Defendants believe that no showing of a specific motivation to combine prior art is required to combine the references disclosed in the attached charts; there was a reason to make each combination, each combination of art would have produced no unexpected results, and each combination at most would simply represent a known alternative to one of ordinary skill in the art. *See KSR Int'l Co. v. Teleflex, Inc.*, 550 U.S. 398, 414–18 (2007) (rejecting the Federal Circuit's "rigid" application of the teaching, suggestion, or motivation to combine test instead espousing an "expansive and flexible" approach). Indeed, the Supreme Court held that a person of ordinary skill in the art is "a person of ordinary creativity, not an automaton" and "in many cases a person of ordinary skill in the art will be able to fit the teachings of multiple patents together like a pieces of a puzzle." *Id.* at 420–21.

Nevertheless, in keeping with the Local Patent Rules, in addition to the information contained elsewhere in these contentions, Defendants identify additional motivations and reasons to combine the cited art. A person of ordinary skill in the art would have been motivated to combine the primary and additional prior art references as set forth above and in Appendices A–C. Multiple teachings, suggestions, and/or reasons to modify any of the references and/or to combine any two or more of the references come from many sources, including the prior art (specific and as a whole), common knowledge, common sense, predictability, expectations, industry trends, design incentives or need, market demand or pressure, market forces, obvious to try, the nature of the problem faced, and/or knowledge possessed by one of ordinary skill in the art.[11] In addition, the patentee admits in the intrinsic record, including the specification and

[11] Defendants reserve the right to present qualified expert testimony on any or all of these items.

prosecution history of the Asserted Patents, that many of the claimed features were conventional and known in the art.

In general, a claimed invention is unpatentable if the differences between it and the prior art "are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art." 35 U.S.C. § 103(a); *Graham v. John Deere Co.*, 383 U.S. 1, 13–14 (1966). The ultimate determination of whether an invention is or is not obvious is a legal conclusion based on underlying factual inquiries including: "(1) the scope and content of the prior art; (2) the level of ordinary skill in the art; (3) the differences between the claimed invention and the prior art; and (4) objective evidence of nonobviousness." *Miles Labs., Inc. v. Shandon, Inc.*, 997 F.2d 870, 877 (Fed. Cir. 1993).

KSR International Co. v. Teleflex Inc., et al., 550 U.S. 398 (2007) ("*KSR*"), reaffirmed *Graham*, holding that a claimed invention can be obvious even if there is no teaching, suggestion, or motivation for combining the prior art to produce that invention. In determining whether a claim is obvious, "[o]ften, it will be necessary for a court to look to interrelated teachings of multiple patents; the effects of demands known to the design community or present in the marketplace; and the background knowledge possessed by a person having ordinary skill in the art, all in order to determine whether there was an apparent reason to combine the known elements in the fashion claimed by the patent at issue." *Id.* at 418. In determining whether a claim is obvious, "a court can take account of the inferences and creative steps that a person of ordinary skill in the art would employ." *Id.* When prior art elements are combined according to known methods to yield predictable results, the claimed invention is obvious. *Id.* at 417. In addition, "[o]ne of the ways in which a patent's subject matter can be proved obvious is by noting that there existed at the time of the invention a known problem for which there was an obvious solution

encompassed by the patent's claims." *Id.* at 419–20. "Under the correct analysis, any need or problem known in the field of endeavor at the time of invention and addressed by the patent can provide a reason for combining the elements in the manner claimed." *Id.* at 420.

Any suggested obviousness combinations set forth herein are in the alternative to Defendants' anticipation contentions and are not to be construed to suggest that any reference included in any combination is not anticipatory in its own right or is not the basis for a single-reference obviousness defense. In particular, Defendants are currently unaware of the extent, if any, to which Plaintiff will contend that certain limitations of the Asserted Claims are not disclosed in the art identified by Defendants as anticipatory. To the extent that an issue arises with respect to any such claim limitation, Defendants reserve the right to identify other references and combinations, which may make obvious the allegedly missing limitation in the disclosed system or method.

The rationale to combine or modify prior art references is significantly stronger when the references seek to solve the same problem, come from the same field, and correspond well. *In re Inland Steel Co.*, 265 F.3d 1354, 1362–64 (Fed. Cir. 2001).

In view of the Supreme Court's *KSR* decision, the PTO issued, and updated, a set of Examination Guidelines. *See* Examination Guidelines for Determining Obviousness Under 35 U.S.C. § 103 in view of the Supreme Court Decision in *KSR International Co. v. Teleflex, Inc.*, 72 Fed. Reg. 57526 (October 10, 2007); Examination Guidelines Update: Development in the Obviousness Inquiry After *KSR v. Teleflex*, 75 Fed. Reg. 53643-60 (September 2010); *see also* MPEP § 2141 (https://www.uspto.gov/web/offices/pac/mpep/s2141.html) (accessed July 6, 2022). These Guidelines summarized the *KSR* decision and subsequent case law, as well as identified

various rationales for finding a claim obvious, including those based on other precedents. Those rationales include:

(1) Combining prior art elements according to known methods to yield predictable results;

(2) Simple substitution of one known element for another to obtain predictable results;

(3) Use of known technique to improve similar devices (methods, or products) in the same way;

(4) Applying a known technique to a known device (method, or product) ready for improvement to yield predictable results;

(5) "Obvious to try" – choosing from a finite number of identified, predictable solutions, with a reasonable expectation of success;

(6) Known work in one field of endeavor may prompt variations of it for use in either the same field or a different one based on design incentives or other market forces if the variations would have been predictable to one of ordinary skill in the art; and

(7) Some teaching, suggestion, or motivation in the prior art that would have led one of ordinary skill to modify the prior art reference or to combine prior art reference teachings to arrive at the claimed invention.

Defendants contend that one or more of these rationales apply in considering the obviousness of the Asserted Claims of the Asserted Patents.

To the extent that prior art identified by Defendants as anticipatory are found not to anticipate the Asserted Claims: (1) the prior art establishes that the claimed subject matter was obvious to a person of ordinary skill in the art at the time of the alleged invention; (2) the claims are nevertheless unpatentable because the Asserted Claims contain nothing that goes beyond "ordinary innovation"; (3) no Asserted Claim goes beyond combining known elements to achieve predictable results (particularly in the predictable art(s) of the Asserted Patent) or does more than choose between clear alternatives known to those of skill in the art; and/or (4) the prior art renders the Asserted Claims obvious either alone or in combination with each other or one or more of the other references identified in these Invalidity Contentions.

Motivation to make the proposed combinations of prior art references and knowledge of one skilled in the art generally exists within the references themselves as well as within the knowledge of one skilled in the art in the relevant time frame. Below are exemplary specific motivations to combine references.

For example, it would have been obvious to try combining the prior art references identified above because there were only a finite number of predictable solutions and/or because known work in one field or endeavor prompted variations based on predictable design incentives and/or market forces either in the same field or a different one. Indeed, because each of these references are generally in the same field (*e.g.*, cable and/or satellite delivery systems) and/or are directed to solving the same alleged problems, including as set forth in the aforementioned claim charts, a person of ordinary skill in the art would be motivated to look for solutions in other references in that field or that solve the same alleged problems.

Relatedly, one of ordinary skill in the art would have been motivated to create combinations identified in these contentions using: known methods to yield predictable results; known techniques in the same way; a simple substitution of one known, equivalent element for another to obtain predictable results; and/or teaching, suggestion, or motivation in the prior art generally. Also, market forces in the industry, and the desire to improve features and performance, would motivate the addition of features to systems as they become available, become smaller, become less expensive, become more commonly used, provide better performance, reduce costs, or predictably achieve other clearly desirable results.

Many of these prior art references cite to, rely upon, incorporate, or are described as an inherent part of one another, including as set forth in the aforementioned claim charts. To the extent such protocols or standards are not already considered inherent to or part of such references,

a person of ordinary skill in the art would be motivated to combine their teachings to achieve predictable results.

Certain of the aforementioned prior art references have the same prior art author(s). A person of ordinary skill in the art would be motivated to combine the work of the same prior art author. Similarly, certain of the prior art references involved the same firms or entities in their development, such as Hughes Network Systems or Hughes Electronics Company.

As shown in the attached Exhibits, each of the references identified comes from the same field. The problems sought to be solved by the identified references and systems were the same ones that had already been solved in the prior art. Indeed, the Asserted Claims recite one of a fine number of known, available alternatives to solve these known problems. The Asserted Claims simply combine previously known methods in a way that was explicitly and implicitly taught and suggested in the prior art. Implementing the teachings of the references identified herein would achieve improved performance.

The Asserted Claims are further obvious in view of the admitted prior art in the specification and file histories of the Asserted Patents. That is, the Asserted Patents themselves admit that certain features and claim elements were known in the prior art before the effective date of the Asserted Patents. Defendants reserve the right to rely on any admissions in the Asserted Patents as part of any obviousness combination, as part of the motivation to combine, and also to explain the state of the art at the time of the Asserted Patents.

B. Specific Motivations for Making Combinations of Prior Art

As explained above, Defendants contend that a person of ordinary skill in the art would have been motivated to combine any of the primary references in these Invalidity Contentions with (1) any other primary reference, (2) any reference disclosed in Appendices A–C as disclosing a limitation missing in a primary reference, (3) any statements made in the intrinsic record of the

Asserted Patents, and/or (4) the knowledge of one of ordinary skill in the art. By way of example only, Defendants provide the following exemplary combinations and some of the reasons a person of ordinary skill in the art would be motivated to combine references.

1. '576 Patent

a. Combinations Based on Ardemagni

To the extent Ardemagni does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine Ardemagni with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
Basawapatna	• Ardemagni and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
U.S. Patent No. 6,970,717 ("Behrens")	• Ardemagni and Behrens relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Behrens would have yielded predictable and desirable results of receiving,

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Behrens with respect to digital processing of RF signals with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Behrens would have been the application of known techniques (*e.g.*, digital processing of RF signals) to known products/systems to yield predictable results.
Carnero	• Ardemagni and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals) to known products/systems to yield predictable results.
Davis '055	• Ardemagni and Davis '055 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals,

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with respect to connecting multiple indoor units to at least one satellite antenna via a local area network with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Davis '055 would have been the application of known techniques (*e.g.*, connecting multiple indoor units to at least one satellite antenna via a local area network) to known products/systems to yield predictable results.
Davis '730	• Ardemagni and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results.
International Published Patent Application No. WO 00/004704 ("Ellis")	• Ardemagni and Ellis relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Ellis would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	single cable. For example, a POSITA would have been motivated to combine the disclosure of Ellis with respect to the interactive television program guide system with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Ellis would have been the application of known techniques (*e.g.*, interactive television program guide system) to known products/systems to yield predictable results.
Gregoire	• Ardemagni and Gregoire relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Gregoire would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gregoire with respect to distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Gregoire would have been the application of known techniques (*e.g.*, distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal) to known products/systems to yield predictable results.
Inose	• Ardemagni and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Inose would have yielded predictable and desirable results of receiving,

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
James	• Ardemagni and James relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.
Kang	• Ardemagni and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals,

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.
Lovinggood	• Ardemagni and Lovinggood relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Lovinggood would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Lovinggood with respect to digital processing of received transponder signals with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Lovinggood would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Mutzig	• Ardemagni and Mutzig relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Mutzig would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals,

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Mutzig with respect to the simultaneous reception of multiple TV channels retransmitted by satellites with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Mutzig would have been the application of known techniques (*e.g.*, simultaneous reception of multiple TV channels retransmitted by satellites) to known products/systems to yield predictable results.
Petruzzelli	• Ardemagni and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Pugel '200	• Ardemagni and Pugel '200 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Pugel '200 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	been motivated to combine the disclosure of Pugel '200 with respect to digital processing of received transponder signals with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Pugel '200 would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Williams '419	• Ardemagni and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Williams '873	• Ardemagni and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	receiver units with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Gurantz	• Ardemagni and Gurantz relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Gurantz would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gurantz with respect to splitting the signal for delivery to multiple set-top boxes with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Gurantz would have been the application of known techniques (*e.g.*, splitting the signal for delivery to multiple set-top boxes) to known products/systems to yield predictable results.
U.S. Patent No. 6,430,742 ("Chanteau")	• Ardemagni and Chanteau relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Chanteau would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Chanteau with respect to broadcasting digital data channels with Ardemagni's system for distributing television and telecommunication services.

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	• Combining Ardemagni and Chanteau would have been the application of known techniques (*e.g.*, broadcasting digital data channels) to known products/systems to yield predictable results.
U.S. Patent No. 3,051,938 ("Levy")	• Ardemagni and Levy relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Ardemagni and Levy would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Levy with respect to converting digital signals to analog signals with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Levy would have been the application of known techniques (*e.g.*, converting digital signals to analog signals) to known products/systems to yield predictable results.
U.S. Patent No. 7,359,447 ("Sage")	• Ardemagni and Sage relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Ardemagni and Sage would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Sage with respect to combining digital signals with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Sage would have been the application of known techniques (*e.g.*, combining digital signals) to known products/systems to yield predictable results.
Oishi	• Ardemagni and Oishi relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Oishi would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Oishi with respect to the frequency conversion table with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Oishi would have been the application of known techniques (*e.g.*, the frequency conversion table) to known products/systems to yield predictable results.
U.S. Patent No. 7,376,387 ("Eck")	• Ardemagni and Eck relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Eck would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Eck with respect to storing a translation table with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Eck would have been the application of known techniques (*e.g.*, storing a translation table) to known products/systems to yield predictable results.
U.S. Patent No. 5,724,091 ("Freeman")	• Ardemagni and Freeman relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Freeman would have yielded predictable and desirable results of receiving,

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Freeman with respect to transmitting and combining digital signals with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Freeman would have been the application of known techniques (*e.g.*, transmitting and combining digital signals) to known products/systems to yield predictable results.
Japanese Published Unexamined Patent Application JP 2001/128138 ("Ishizaki")	• Ardemagni and Ishizaki relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Ishizaki would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ishizaki with respect to distributing multiplexed signals to subscribers on the same physical channel with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Ishizaki would have been the application of known techniques (*e.g.*, distributing multiplexed signals to subscribers on the same physical channel) to known products/systems to yield predictable results.
Japanese Published Unexamined Patent Application JP 2002/135745 ("Ogami")	• Ardemagni and Ogami relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Ogami would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ogami with respect to distributing a signal received by an antenna to multiple rooms via a coaxial cable with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Ogami would have been the application of known techniques (*e.g.*, distributing a signal received by an antenna to multiple rooms via a coaxial cable) to known products/systems to yield predictable results.

b. Combinations Based on Basawapatna

To the extent Basawapatna does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine Basawapatna with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
Ardemagni	• Basawapatna and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Behrens	• Basawapatna and Behrens relate to the same and/or related field because both relate to distributing broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
	Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Behrens would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Behrens with respect to digital processing of RF signals with Basawapatna's system for distributing television and telecommunication services. • Combining Basawapatna and Behrens would have been the application of known techniques (*e.g.*, digital processing of RF signals) to known products/systems to yield predictable results.
Carnero	• Basawapatna and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals) to known products/systems to yield predictable results.
Davis '055	• Basawapatna and Davis '055 relate to the same and/or related field because both relate to distributing broadband

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
	signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with respect to connecting multiple indoor units to at least one satellite antenna via a local area network with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Davis '055 would have been the application of known techniques (*e.g.*, connecting multiple indoor units to at least one satellite antenna via a local area network) to known products/systems to yield predictable results.
Davis '730	• Basawapatna and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results.
Ellis	• Basawapatna and Ellis relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Ellis would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ellis with respect to the interactive television program guide system with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Ellis would have been the application of known techniques (*e.g.*, interactive television program guide system) to known products/systems to yield predictable results.
Gregoire	• Basawapatna and Gregoire relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Gregoire would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gregoire with respect to distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Gregoire would have been the application of known techniques (*e.g.*, distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
Inose	• Basawapatna and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
James	• Basawapatna and James relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
Kang	• Basawapatna and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.
Lovinggood	• Basawapatna and Lovinggood relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Lovinggood would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Lovinggood with respect to digital processing of received transponder signals with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Lovinggood would have been the application of known techniques (*e.g.*, digital processing

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
	of received transponder signals) to known products/systems to yield predictable results.
Mutzig	• Basawapatna and Mutzig relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Mutzig would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Mutzig with respect to the simultaneous reception of multiple TV channels retransmitted by satellites with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Mutzig would have been the application of known techniques (*e.g.*, simultaneous reception of multiple TV channels retransmitted by satellites) to known products/systems to yield predictable results.
Petruzzelli	• Basawapatna and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
	from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Pugel '200	• Basawapatna and Pugel '200 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Pugel '200 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Pugel '200 with respect to digital processing of received transponder signals with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Pugel '200 would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Williams '419	• Basawapatna and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
Williams '873	• Basawapatna and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Gurantz	• Basawapatna and Gurantz relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Gurantz would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gurantz with respect to splitting the signal for delivery to multiple set-top boxes with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Gurantz would have been the application of known techniques (*e.g.*, splitting the signal for delivery to multiple set-top boxes) to known products/systems to yield predictable results.
Chanteau	• Basawapatna and Chanteau relate to the same and/or related field because both relate to distributing broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
	Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Chanteau would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Chanteau with respect to broadcasting digital data channels with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Chanteau would have been the application of known techniques (*e.g.*, broadcasting digital data channels) to known products/systems to yield predictable results.
Levy	• Basawapatna and Levy relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Basawapatna and Levy would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Levy with respect to converting digital signals to analog signals with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Levy would have been the application of known techniques (*e.g.*, converting digital signals to analog signals) to known products/systems to yield predictable results.
Sage	• Basawapatna and Sage relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Basawapatna and Sage would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
	single cable. For example, a POSITA would have been motivated to combine the disclosure of Sage with respect to combining digital signals with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Sage would have been the application of known techniques (*e.g.*, combining digital signals) to known products/systems to yield predictable results.
Oishi	• Basawapatna and Oishi relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Oishi would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Oishi with respect to the frequency conversion table with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Oishi would have been the application of known techniques (*e.g.*, the frequency conversion table) to known products/systems to yield predictable results.
Eck	• Basawapatna and Eck relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Eck would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Eck with respect to storing a translation table with Basawapatna's system for

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
	distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Eck would have been the application of known techniques (*e.g.*, storing a translation table) to known products/systems to yield predictable results.
Freeman	• Basawapatna and Freeman relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Freeman would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Freeman with respect to transmitting and combining digital signals with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Freeman would have been the application of known techniques (*e.g.*, transmitting and combining digital signals) to known products/systems to yield predictable results.
Ishizaki	• Basawapatna and Ishizaki relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Ishizaki would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ishizaki with respect to distributing multiplexed signals to subscribers on the same physical channel with Basawapatna's system for distributing the broadband signal to a plurality of user devices.

Reference to Combine	Exemplary Motivation(s) to Combine with Basawapatna
	• Combining Basawapatna and Ishizaki would have been the application of known techniques (*e.g.*, distributing multiplexed signals to subscribers on the same physical channel) to known products/systems to yield predictable results.
Ogami	• Basawapatna and Ogami relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Basawapatna and Ogami would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ogami with respect to distributing a signal received by an antenna to multiple rooms via a coaxial cable with Basawapatna's system for distributing the broadband signal to a plurality of user devices. • Combining Basawapatna and Ogami would have been the application of known techniques (*e.g.*, distributing a signal received by an antenna to multiple rooms via a coaxial cable) to known products/systems to yield predictable results.

c. Combinations Based on Carnero

To the extent Carnero does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine Carnero with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Carnero
Ardemagni	• Carnero and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Carnero
	• The combination of Carnero and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Carnero's system for distributing television satellite signals in a community antenna system. • Combining Carnero and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Basawapatna	• Carnero and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Carnero and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Carnero's system for distributing television satellite signals in a community antenna system. • Combining Carnero and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
Behrens	• Behrens and Carnero relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Processing selected transponder signals in the digital domain and converting the selected signal back to analog prior to combining would have been obvious in view of Carnero and Behrens and would have yielded predictable and desirable results of realizing resource-efficient digital processing while

Reference to Combine	Exemplary Motivation(s) to Combine with Carnero
	ensuring the signal would be compatible with existing components in satellite television systems, such as integrated receiver decoders. • Combining the disclosures of Carnero and Behrens would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Behrens's digital processing of RF signals with Carnero's system for distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Carnero and Behrens would have been the application of known techniques to similar products/systems.
Chanteau	• Chanteau and Carnero relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building). • Combining the disclosures of Carnero and Chanteau would have been a logical extension of the existing and described signal processing techniques. • Combining Carnero and Chanteau would have been the application of known techniques to similar products/systems.
Davis '055	• Carnero and Davis '055 relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Digitizing the plurality of satellite broadband signals in the ODU prior to selecting and extracting selected transponder signals would have been obvious in view of Davis '055 and Carnero and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs.

Reference to Combine	Exemplary Motivation(s) to Combine with Carnero
	• Combining the disclosures of Davis '055 and Carnero would have been a logical extension of the existing and described satellite signal distribution and signal processing techniques, including wireless communication between IRDs and an ODU. • Additionally, a POSITA would have been motivated to combine Davis '055's digital processing of received transponder signals with Carnero's system for distributing television satellite signals in a community antenna system, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Davis '055 and Carnero would have been the application of known techniques to similar products/systems.
Davis '730	• Carnero and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Carnero and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Carnero's system for distributing television satellite signals in a community antenna system. • Combining Carnero and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results.
Ellis	• Ellis and Carnero relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels.

Reference to Combine	Exemplary Motivation(s) to Combine with Carnero
	• Maintaining a channel translation table at the ODU, the channel translation table specifying assigned frequency slots for transponder signals in the composite signal, and providing the channel translation table to IRDs would have been obvious in view of Carnero and Ellis and would have yielded predictable and desirable results of facilitating user selection of and access to satellite television channels. • Combining the disclosures of Carnero and Ellis would have been a logical extension of the existing and described satellite signal distribution techniques. • Additionally, a POSITA would have been motivated to combine Ellis's interactive television program guide system with Carnero's system for distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to facilitate user selection of and access to satellite television channels. • Combining Carnero and Ellis would have been the application of known techniques to similar products/systems.
Gregoire	• Carnero and Gregoire relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Combining the disclosures of Gregoire and Carnero would have been a logical extension of the existing and described satellite signal distribution and signal processing techniques, including wireless communication between IRDs and an ODU. • Combining Gregoire and Carnero would have been the application of known techniques to similar products/systems.
Inose	• Carnero and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Carnero and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including

Reference to Combine	Exemplary Motivation(s) to Combine with Carnero
	communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Carnero's system for distributing television satellite signals in a community antenna system. • Combining Carnero and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
James	• Carnero and James relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Carnero and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Carnero's system for distributing television satellite signals in a community antenna system. • Combining Carnero and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.
Kang	• Carnero and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Carnero and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to

Reference to Combine	Exemplary Motivation(s) to Combine with Carnero
	receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Carnero's system for distributing television satellite signals in a community antenna system. • Combining Carnero and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.
Lovinggood	• Carnero and Lovinggood relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Digitizing the plurality of satellite broadband signals in the ODU prior to selecting and extracting selected transponder signals would have been obvious in view of Lovinggood and Carnero and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Converting the selected signal back to analog prior to combining would have been obvious in view of Carnero and Lovinggood and would have yielded predictable and desirable results of realizing resource-efficient digital processing while ensuring the signal would be compatible with existing components in satellite television systems, such as integrated receiver decoders. • Combining the disclosures of Lovinggood and Carnero would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Lovinggood's digital processing of received transponder signals with Carnero's system for distributing television satellite signals in a community antenna system, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, to more efficiently provide satellite

Reference to Combine	Exemplary Motivation(s) to Combine with Carnero
	television services to a plurality of users requesting various transponder signals. • Combining Lovinggood and Carnero would have been the application of known techniques to similar products/systems.
Mutzig	• Carnero and Mutzig relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Carnero and Mutzig would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Mutzig with respect to simultaneous reception of multiple TV channels retransmitted by satellites with Carnero's system for distributing television satellite signals in a community antenna system. • Combining Carnero and Mutzig would have been the application of known techniques (e.g., simultaneous reception of multiple TV channels retransmitted by satellites) to known products/systems to yield predictable results.
Oishi	• Oishi and Carnero relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Maintaining a channel translation table at the ODU, the channel translation table specifying assigned frequency slots for transponder signals in the composite signal, and providing the channel translation table to IRDs would have been obvious in view of Carnero and Oishi and would have yielded predictable and desirable results of facilitating user selection of and access to satellite television channels. • Combining the disclosures of Carnero and Oishi would have been a logical extension of the existing and described satellite signal distribution techniques.

Reference to Combine	Exemplary Motivation(s) to Combine with Carnero
	• Additionally, a POSITA would have been motivated to combine Oishi's television signal distributor and receiver apparatuses (including frequency conversion table) with Carnero's system for distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to facilitate user selection of and access to satellite television channels. • Combining Carnero and Oishi would have been the application of known techniques to similar products/systems.
Petruzzelli	• Carnero and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Carnero and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with Carnero's system for distributing television satellite signals in a community antenna system. • Combining Carnero and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Pugel '200	• Carnero and Pugel '200 relate to the same and/or related field because both relate to distributing satellite transponder channel signals at a customer/user premises (e.g., a home or office building). • Digitizing the plurality of satellite broadband signals in the ODU prior to selecting and extracting selected transponder signals would have been obvious in view of Pugel '200 and Carnero and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs.

Reference to Combine	Exemplary Motivation(s) to Combine with Carnero
	• Combining the disclosures of Pugel '200 and Carnero would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Pugel '200's digital processing of received transponder signals with Carnero's system for distributing television satellite signals in a community antenna system, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Pugel '200 and Carnero would have been the application of known techniques to similar products/systems.
Williams '419	• Carnero and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Carnero and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with Carnero's system for distributing television satellite signals in a community antenna system. • Combining Carnero and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Williams '873	• Carnero and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Carnero and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals,

Reference to Combine	Exemplary Motivation(s) to Combine with Carnero
	including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Carnero's system for distributing television satellite signals in a community antenna system. • Combining Carnero and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.

d. Combinations Based on Davis '055

To the extent Davis '055 does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine Davis '055 with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '055
Ardemagni	• Davis '055 and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '055 and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis and Ardemagni with respect to distributing television and telecommunication services with Davis '055's system for connecting multiple indoor units to at least one satellite antenna via a local area network. • Combining Davis '055 and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '055
Basawapatna	• Davis '055 and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '055 and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Davis '055's system for connecting multiple indoor units to at least one satellite antenna via a local area network. • Combining Davis '055 and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
Behrens	• Behrens and Davis '055 relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Converting the selected signal to analog prior to combining would have been obvious in view of Davis '055 and Behrens and would have yielded predictable and desirable results of ensuring compatibility with existing components in satellite television systems, such as integrated receiver decoders. • Combining the disclosures of Davis '055 and Behrens would have been a logical extension of the existing and described signal processing techniques. • Combining Davis '055 and Behrens would have been the application of known techniques to similar products/systems.
Carnero	• Carnero and Davis '055 relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels.

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '055
	• Selecting and extracting selected transponder signals after digitizing the plurality of satellite broadband signals in the ODU would have been obvious in view of Carnero and Davis '055 and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Davis '055 and Carnero would have been a logical extension of the existing and described satellite signal distribution and signal processing techniques. • Additionally, a POSITA would have been motivated to combine Carnero's system for distributing television satellite signals in a community antenna system, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, with Davis '055's digital processing of received transponder signals to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Davis '055 and Carnero would have been the application of known techniques to similar products/systems.
Chanteau	• Chanteau and Davis '055 relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building). • Combining the disclosures of Davis '055 and Chanteau would have been a logical extension of the existing and described signal processing techniques. • Combining Davis '055 and Chanteau would have been the application of known techniques to similar products/systems.
Davis '730	• Davis '055 and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '055 and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals,

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '055
	including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Davis '055's system for connecting multiple indoor units to at least one satellite antenna via a local area network. • Combining Davis '055 and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results. • Davis '730 and Davis '055 share a common inventor and original assignee.
Ellis	• Ellis and Davis '055 relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Maintaining a channel translation table at the ODU, the channel translation table specifying assigned frequency slots for transponder signals in the composite signal, and providing the channel translation table to IRDs would have been obvious in view of Davis '055 and Ellis and would have yielded predictable and desirable results of facilitating user selection of and access to satellite television channels. • Combining the disclosures of Davis '055 and Ellis would have been a logical extension of the existing and described satellite signal distribution techniques. • Additionally, a POSITA would have been motivated to combine Ellis's interactive television program guide system with Davis '055's LAN-based satellite antenna/satellite multiswitch to more efficiently provide satellite television services to facilitate user selection of and access to satellite television channels. • Combining Davis '055 and Ellis would have been the application of known techniques to similar products/systems.

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '055
Gregoire	• Gregoire and Davis '055 relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Selecting and extracting selected transponder signals after digitizing the plurality of satellite broadband signals in the ODU would have been obvious in view of Davis '055 and Gregoire and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Davis '055 and Gregoire would have been a logical extension of the existing and described satellite signal distribution and signal processing techniques. • Additionally, a POSITA would have been motivated to combine Gregoire's system for distribution of direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, with Davis '055's digital processing of received transponder signals with Gregoire's system for distribution of direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Davis '055 and Gregoire would have been the application of known techniques to similar products/systems. • Gregoire explains that its "disclosure will focus the invention's application on the" Hughes DTV system, and Davis '055 was originally assigned to Hughes.
Inose	• Davis '055 and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '055
	• The combination of Davis '055 and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Davis '055's system for connecting multiple indoor units to at least one satellite antenna via a local area network. • Combining Davis '055 and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
James	• Davis '055 and James relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '055 and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Davis '055's system for connecting multiple indoor units to at least one satellite antenna via a local area network. • Combining Davis '055 and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.
Kang	• Davis '055 and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '055 and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals,

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '055
	including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to its system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable system with Davis '055's system for connecting multiple indoor units to at least one satellite antenna via a local area network. • Combining Davis '055 and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.
Lovinggood	• Davis '055 and Lovinggood relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '055 and Lovinggood would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Lovinggood with respect to its digital processing of received transponder signals with Davis '055's system for connecting multiple indoor units to at least one satellite antenna via a local area network. • Combining Davis '055 and Lovinggood would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Mutzig	• Mutzig and Davis '055 relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Selecting and extracting selected transponder signals after digitizing the plurality of satellite broadband signals in the

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '055
	ODU would have been obvious in view of Davis '055 and Mutzig and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Davis '055 and Mutzig would have been a logical extension of the existing and described satellite signal distribution and signal processing techniques, including wireless communication between IRDs and an ODU. • Additionally, a POSITA would have been motivated to combine Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, with Davis '055's digital processing of received transponder signals, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Davis '055 and Mutzig would have been the application of known techniques to similar products/systems.
Petruzzelli	• Davis '055 and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '055 and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with Davis '055's system for connecting multiple indoor units to at least one satellite antenna via a local area network. • Combining Davis '055 and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '055
	from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Oishi	• Oishi and Davis '055 relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Maintaining a channel translation table at the ODU, the channel translation table specifying assigned frequency slots for transponder signals in the composite signal, and providing the channel translation table to IRDs would have been obvious in view of Davis '055 and Oishi and would have yielded predictable and desirable results of facilitating user selection of and access to satellite television channels. • Combining the disclosures of Davis '055 and Oishi would have been a logical extension of the existing and described satellite signal distribution techniques. • Additionally, a POSITA would have been motivated to combine Oishi's television signal distributor and receiver apparatuses (including frequency conversion table) with Davis '055's LAN-based satellite antenna/satellite multiswitch to more efficiently provide satellite television services to facilitate user selection of and access to satellite television channels. • Combining Davis '055 and Oishi would have been the application of known techniques to similar products/systems.
Pugel '200	• Davis '055 and Pugel '200 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '055 and Pugel '200 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Pugel '200 with respect to digital processing of received transponder signals

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '055
	with Davis '055's system for connecting multiple indoor units to at least one satellite antenna via a local area network. • Combining Davis '055 and Pugel '200 would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Williams '419	• Davis '055 and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '055 and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with Davis '055's system for connecting multiple indoor units to at least one satellite antenna via a local area network. • Combining Davis '055 and Williams '419 would have been the application of known techniques (*e.g.*, to distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results. • Williams '419 and Davis '055 share a common original assignee.
Williams '873	• Davis '055 and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '055 and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Davis '055's system for connecting

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '055
	multiple indoor units to at least one satellite antenna via a local area network. • Combining Davis '055 and Williams '873 would have been the application of known techniques (*e.g.*, to distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results. • Williams '873 and Davis '055 share a common original assignee.

e. Combinations Based on Davis '730

To the extent Davis '730 does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine Davis '730 with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
Ardemagni	• Davis '730 and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
Basawapatna	• Davis '730 and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
Behrens	• Davis '730 and Behrens relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Behrens would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Behrens with respect to digital processing of RF signals with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Behrens would have been the application of known techniques (*e.g.*, digital processing of RF signals) to known products/systems to yield predictable results.
Carnero	• Davis '730 and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
	• The combination of Davis '730 and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals) to known products/systems to yield predictable results.
Davis '055	• Davis '730 and Davis '055 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with respect to connecting multiple indoor units to at least one satellite antenna via a local area network with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Davis '055 would have been the application of known techniques (*e.g.*, connecting multiple indoor units to at least one satellite antenna via a local area network) to known products/systems to yield predictable results. • Davis '730 and Davis '055 share a common inventor and original assignee.

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
Ellis	• Davis '730 and Ellis relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Ellis would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ellis with respect to the interactive television program guide system with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Ellis would have been the application of known techniques (*e.g.*, interactive television program guide system) to known products/systems to yield predictable results.
Gregoire	• Davis '730 and Gregoire relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Gregoire would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gregoire with respect to distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Gregoire would have been the application of known techniques (*e.g.*, distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
	transponders on a composite signal) to known products/systems to yield predictable results. • Gregoire explains that its "disclosure will focus the invention's application on the" Hughes DTV system, and Davis '730 was originally assigned to Hughes.
Inose	• Davis '730 and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
James	• Davis '730 and James relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Davis '730's system for distributing multiple satellite signals over a single cable line.

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
	• Combining Davis '730 and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results. • Davis '730 and James would be obvious to combine because both share a common assignee.
Kang	• Davis '730 and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.
Lovinggood	• Davis '730 and Lovinggood relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Lovinggood would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
	been motivated to combine the disclosure of Lovinggood with respect to digital processing of received transponder signals with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Lovinggood would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Mutzig	• Davis '730 and Mutzig relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Mutzig would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Mutzig with respect to the simultaneous reception of multiple TV channels retransmitted by satellites with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Mutzig would have been the application of known techniques (*e.g.*, simultaneous reception of multiple TV channels retransmitted by satellites) to known products/systems to yield predictable results.
Petruzzelli	• Davis '730 and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
	respect to combining signals from the ODU to be transmitted by a single cable with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Pugel '200	• Davis '730 and Pugel '200 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Pugel '200 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Pugel '200 with respect to digital processing of received transponder signals with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Pugel '200 would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Williams '419	• Davis '730 and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
	receiver units with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results. • Williams '419 and Davis '730 share a common original assignee.
Williams '873	• Davis '730 and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Williams '873 and Davis '730 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results. • Williams '873 and Davis '730 share a common original assignee.
Gurantz	• Davis '730 and Gurantz relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Gurantz would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
	over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gurantz with respect to splitting the signal for delivery to multiple set-top boxes with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Gurantz would have been the application of known techniques (*e.g.*, splitting the signal for delivery to multiple set-top boxes) to known products/systems to yield predictable results.
Chanteau	• Davis '730 and Chanteau relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Chanteau would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Chanteau with respect to broadcasting digital data channels with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Chanteau would have been the application of known techniques (*e.g.*, broadcasting digital data channels) to known products/systems to yield predictable results.
Levy	• Davis '730 and Levy relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Davis '730 and Levy would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Levy with respect to converting digital signals to analog signals with Davis '730's system for distributing multiple satellite signals over a single cable line.

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
	• Combining Davis '730 and Levy would have been the application of known techniques (*e.g.*, converting digital signals to analog signals) to known products/systems to yield predictable results.
Sage	• Davis '730 and Sage relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Davis '730 and Sage would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Sage with respect to combining digital signals with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Sage would have been the application of known techniques (*e.g.*, combining digital signals) to known products/systems to yield predictable results.
Oishi	• Davis '730 and Oishi relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Oishi would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Oishi with respect to the frequency conversion table with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Oishi would have been the application of known techniques (*e.g.*, the frequency conversion table) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
Eck	• Davis '730 and Eck relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Eck would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Eck with respect to storing a translation table with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Eck would have been the application of known techniques (*e.g.*, storing a translation table) to known products/systems to yield predictable results.
Freeman	• Davis '730 and Freeman relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Freeman would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Freeman with respect to transmitting and combining digital signals with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Freeman would have been the application of known techniques (*e.g.*, transmitting and combining digital signals) to known products/systems to yield predictable results.
Ishizaki	• Davis '730 and Ishizaki relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Davis '730
	• The combination of Davis '730 and Ishizaki would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ishizaki with respect to distributing multiplexed signals to subscribers on the same physical channel with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Ishizaki would have been the application of known techniques (*e.g.*, distributing multiplexed signals to subscribers on the same physical channel) to known products/systems to yield predictable results.
Ogami	• Davis '730 and Ogami relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Davis '730 and Ogami would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ogami with respect to distributing a signal received by an antenna to multiple rooms via a coaxial cable with Davis '730's system for distributing multiple satellite signals over a single cable line. • Combining Davis '730 and Ogami would have been the application of known techniques (*e.g.*, distributing a signal received by an antenna to multiple rooms via a coaxial cable) to known products/systems to yield predictable results.

f. Combinations Based on Gregoire

To the extent Gregoire does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated

to combine Gregoire with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Gregoire
Ardemagni	• Gregoire and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Gregoire and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Gregoire's system for distribution of direct-to-home wireless services. • Combining Gregoire and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Basawapatna	• Gregoire and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Gregoire and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Gregoire's system for distribution of direct-to-home wireless services. • Combining Gregoire and Basawapatna would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Gregoire
Behrens	• Behrens and Gregoire relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Processing selected transponder signals in the digital domain and converting the selected signal back to analog prior to combining would have been obvious in view of Gregoire and Behrens and would have yielded predictable and desirable results of realizing resource-efficient digital processing while ensuring the signal would be compatible with existing components in satellite television systems, such as integrated receiver decoders. • Combining the disclosures of Gregoire and Behrens would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Behrens's digital processing of RF signals with Gregoire's system for distribution of direct-to-home wireless services (such as satellite television) to more efficiently provide those services to a plurality of users requesting various transponder signals. • Combining Gregoire and Behrens would have been the application of known techniques to similar products/systems.
Carnero	• Gregoire and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Gregoire and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals with Gregoire's system for distribution of direct-to-home wireless services.

Reference to Combine	Exemplary Motivation(s) to Combine with Gregoire
	• Combining Gregoire and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals) to known products/systems to yield predictable results.
Chanteau	• Chanteau and Gregoire relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building). • Combining the disclosures of Gregoire and Chanteau would have been a logical extension of the existing and described signal processing techniques. • Combining Gregoire and Chanteau would have been the application of known techniques to similar products/systems.
Davis '055	• Gregoire and Davis '055 relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Digitizing the plurality of satellite broadband signals in the ODU prior to selecting and extracting selected transponder signals would have been obvious in view of Davis '055 and Gregoire and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Davis '055 and Gregoire would have been a logical extension of the existing and described satellite signal distribution and signal processing techniques. • Additionally, a POSITA would have been motivated to combine Davis '055's digital processing of received transponder signals with Gregoire's system for distribution of direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, to more

Reference to Combine	Exemplary Motivation(s) to Combine with Gregoire
	efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Davis '055 and Gregoire would have been the application of known techniques to similar products/systems. • Gregoire explains that its "disclosure will focus the invention's application on the" Hughes DTV system, and Davis '055 was originally assigned to Hughes.
Davis '730	• Gregoire and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Gregoire and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Gregoire's system for distribution of direct-to-home wireless services. • Combining Gregoire and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results. • Gregoire explains that its "disclosure will focus the invention's application on the" Hughes DTV system, and Davis '730 was originally assigned to Hughes.
Ellis	• Ellis and Gregoire relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Maintaining a channel translation table at the ODU, the channel translation table specifying assigned frequency slots for transponder signals in the composite signal, and providing the channel translation table to IRDs would have been obvious in view of Gregoire and Ellis and would have

Reference to Combine	Exemplary Motivation(s) to Combine with Gregoire
	yielded predictable and desirable results of facilitating user selection of and access to satellite television channels. • Combining the disclosures of Gregoire and Ellis would have been a logical extension of the existing and described satellite signal distribution techniques. • Additionally, a POSITA would have been motivated to combine Ellis's interactive television program guide system with Gregoire's system for distribution of direct-to-home wireless services to more efficiently provide satellite television services to facilitate user selection of and access to satellite television channels. • Combining Gregoire and Ellis would have been the application of known techniques to similar products/systems.
Inose	• Gregoire and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Gregoire and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Gregoire's system for distribution of direct-to-home wireless services. • Combining Gregoire and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
James	• Gregoire and James relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Gregoire and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a

Reference to Combine	Exemplary Motivation(s) to Combine with Gregoire
	single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Gregoire's system for distribution of direct-to-home wireless services. • Combining Gregoire and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.
Kang	• Gregoire and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Gregoire and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Gregoire's system for distribution of direct-to-home wireless services. • Combining Gregoire and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.
Lovinggood	• Gregoire and Lovinggood relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Digitizing the plurality of satellite broadband signals in the ODU prior to selecting and extracting selected transponder signals would have been obvious in view of Lovinggood and Gregoire and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing

Reference to Combine	Exemplary Motivation(s) to Combine with Gregoire
	flexibility to increase or decrease the number of transponder signals provided to IRDs. • Converting the selected signal back to analog prior to combining would have been obvious in view of Gregoire and Lovinggood and would have yielded predictable and desirable results of realizing resource-efficient digital processing while ensuring the signal would be compatible with existing components in satellite television systems, such as integrated receiver decoders. • Combining the disclosures of Lovinggood and Gregoire would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Lovinggood's digital processing of received transponder signals with Gregoire's system for distribution of direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Lovinggood and Carnero would have been the application of known techniques to similar products/systems.
Mutzig	• Gregoire and Mutzig relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Gregoire and Mutzig would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Mutzig with respect to the simultaneous reception of multiple TV channels retransmitted by satellites with Gregoire's system for distribution of direct-to-home wireless services. • Combining Gregoire and Mutzig would have been the application of known techniques (*e.g.*, the simultaneous

Reference to Combine	Exemplary Motivation(s) to Combine with Gregoire
	reception of multiple TV channels retransmitted by satellites) to known products/systems to yield predictable results.
Petruzzelli	• Gregoire and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Gregoire and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with Gregoire's system for distribution of direct-to-home wireless services. • Combining Gregoire and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Oishi	• Oishi and Gregoire relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Maintaining a channel translation table at the ODU, the channel translation table specifying assigned frequency slots for transponder signals in the composite signal, and providing the channel translation table to IRDs would have been obvious in view of Gregoire and Oishi and would have yielded predictable and desirable results of facilitating user selection of and access to satellite television channels. • Combining the disclosures of Gregoire and Oishi would have been a logical extension of the existing and described satellite signal distribution techniques. • Additionally, a POSITA would have been motivated to combine Oishi's television signal distributor and receiver apparatuses (including frequency conversion table) with Gregoire's system for distribution of direct-to-home wireless

Reference to Combine	Exemplary Motivation(s) to Combine with Gregoire
	services to more efficiently provide satellite television services to facilitate user selection of and access to satellite television channels. • Combining Gregoire and Oishi would have been the application of known techniques to similar products/systems.
Pugel '200	• Gregoire and Pugel '200 relate to the same and/or related field because both relate to distributing satellite transponder channel signals at a customer/user premises (e.g., a home or office building). • Digitizing the plurality of satellite broadband signals in the ODU prior to selecting and extracting selected transponder signals would have been obvious in view of Pugel '200 and Gregoire and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Pugel '200 and Gregoire would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Pugel '200's digital processing of received transponder signals with Gregoire's system for distribution of direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Pugel '200 and Gregoire would have been the application of known techniques to similar products/systems.
Williams '419	• Gregoire and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Gregoire and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals,

Reference to Combine	Exemplary Motivation(s) to Combine with Gregoire
	including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with Gregoire's system for distribution of direct-to-home wireless services. • Combining Gregoire and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results. • Gregoire explains that its "disclosure will focus the invention's application on the" Hughes DTV system, and Williams '419 was originally assigned to Hughes.
Williams '873	• Gregoire and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Gregoire and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Gregoire's system for distribution of direct-to-home wireless services. • Combining Gregoire and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results. • Gregoire explains that its "disclosure will focus the invention's application on the" Hughes DTV system, and Williams '873 was originally assigned to Hughes.

g. Combinations Based on Inose

To the extent Inose does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to

combine Inose with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
Ardemagni	• Inose and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Inose's system for distributing digital broadband signals. • Combining Inose and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Basawapatna	• Inose and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Inose's system for distributing digital broadband signals. • Combining Inose and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
Behrens	• Inose and Behrens relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Behrens would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Behrens with respect to digital processing of RF signals with Inose's system for distributing digital broadband signals. • Combining Inose and Behrens would have been the application of known techniques (*e.g.*, digital processing of RF signals) to known products/systems to yield predictable results.
Carnero	• Inose and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals with Inose's system for distributing digital broadband signals. • Combining Inose and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals) to known products/systems to yield predictable results.
Davis '055	• Inose and Davis '055 relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with respect to connecting multiple indoor units to at least one satellite antenna via a local area network with Inose's system for distributing digital broadband signals. • Combining Inose and Davis '055 would have been the application of known techniques (*e.g.*, connecting multiple indoor units to at least one satellite antenna via a local area network) to known products/systems to yield predictable results.
Davis '730	• Inose and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Inose's system for distributing digital broadband signals. • Combining Inose and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results.
Ellis	• Inose and Ellis relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
	• The combination of Inose and Ellis would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ellis with respect to the interactive television program guide system with Inose's system for distributing digital broadband signals. • Combining Inose and Ellis would have been the application of known techniques (*e.g.*, interactive television program guide system) to known products/systems to yield predictable results.
Gregoire	• Inose and Gregoire relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Gregoire would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gregoire with respect to distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal with Inose's system for distributing digital broadband signals. • Combining Inose and Gregoire would have been the application of known techniques (*e.g.*, distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal) to known products/systems to yield predictable results.
James	• Inose and James relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Inose's system for distributing digital broadband signals. • Combining Inose and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.
Kang	• Inose and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Inose's system for distributing digital broadband signals. • Combining Inose and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.
Lovinggood	• Inose and Lovinggood relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Lovinggood would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Lovinggood with respect to digital processing of received transponder signals with Inose's system for distributing digital broadband signals. • Combining Inose and Lovinggood would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Mutzig	• Inose and Mutzig relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Mutzig would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Mutzig with respect to the simultaneous reception of multiple TV channels retransmitted by satellites with Inose's system for distributing digital broadband signals. • Combining Inose and Mutzig would have been the application of known techniques (*e.g.*, simultaneous reception of multiple TV channels retransmitted by satellites) to known products/systems to yield predictable results.
Petruzzelli	• Inose and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with Inose's system for distributing digital broadband signals. • Combining Inose and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Pugel '200	• Inose and Pugel '200 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Pugel '200 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Pugel '200 with respect to digital processing of received transponder signals with Inose's system for distributing digital broadband signals. • Combining Inose and Pugel '200 would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Williams '419	• Inose and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
	• The combination of Inose and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with Inose's system for distributing digital broadband signals. • Combining Inose and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Williams '873	• Inose and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Inose's system for distributing digital broadband signals. • Combining Inose and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Gurantz	• Inose and Gurantz relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Gurantz would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
	communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gurantz with respect to splitting the signal for delivery to multiple set-top boxes with Inose's system for distributing digital broadband signals. • Combining Inose and Gurantz would have been the application of known techniques (*e.g.*, splitting the signal for delivery to multiple set-top boxes) to known products/systems to yield predictable results.
Chanteau	• Inose and Chanteau relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Chanteau would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Chanteau with respect to broadcasting digital data channels with Inose's system for distributing digital broadband signals. • Combining Inose and Chanteau would have been the application of known techniques (*e.g.*, broadcasting digital data channels) to known products/systems to yield predictable results.
Levy	• Inose and Levy relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Inose and Levy would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Levy with respect to converting digital signals to analog signals with Inose's system for distributing digital broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
	• Combining Inose and Levy would have been the application of known techniques (*e.g.*, converting digital signals to analog signals) to known products/systems to yield predictable results.
Sage	• Inose and Sage relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Inose and Sage would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Sage with respect to combining digital signals with Inose's system for distributing digital broadband signals. • Combining Inose and Sage would have been the application of known techniques (*e.g.*, combining digital signals) to known products/systems to yield predictable results.
Oishi	• Inose and Oishi relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Oishi would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Oishi with respect to the frequency conversion table with Inose's system for distributing digital broadband signals. • Combining Inose and Oishi would have been the application of known techniques (*e.g.*, the frequency conversion table) to known products/systems to yield predictable results.
Eck	• Inose and Eck relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Eck would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Eck with respect to storing a translation table with Inose's system for distributing digital broadband signals. • Combining Inose and Eck would have been the application of known techniques (*e.g.*, storing a translation table) to known products/systems to yield predictable results.
Freeman	• Inose and Freeman relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Freeman would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Freeman with respect to transmitting and combining digital signals with Inose's system for distributing digital broadband signals. • Combining Inose and Freeman would have been the application of known techniques (*e.g.*, transmitting and combining digital signals) to known products/systems to yield predictable results.
Ishizaki	• Inose and Ishizaki relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Ishizaki would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including

Reference to Combine	Exemplary Motivation(s) to Combine with Inose
	communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ishizaki with respect to distributing multiplexed signals to subscribers on the same physical channel with Inose's system for distributing digital broadband signals. • Combining Inose and Ishizaki would have been the application of known techniques (*e.g.*, distributing multiplexed signals to subscribers on the same physical channel) to known products/systems to yield predictable results.
Ogami	• Inose and Ogami relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Inose and Ogami would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ogami with respect to distributing a signal received by an antenna to multiple rooms via a coaxial cable with Inose's system for distributing digital broadband signals. • Combining Inose and Ogami would have been the application of known techniques (*e.g.*, distributing a signal received by an antenna to multiple rooms via a coaxial cable) to known products/systems to yield predictable results.

h. Combinations Based on James

To the extent James does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine James with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with James
Ardemagni	• James and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Basawapatna	• James and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
Behrens	• James and Behrens relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with James
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Behrens would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Behrens with respect to digital processing of RF signals with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Behrens would have been the application of known techniques (*e.g.*, digital processing of RF signals) to known products/systems to yield predictable results.
Carnero	• James and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals) to known products/systems to yield predictable results.
Davis '055	• James and Davis '055 relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with James
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with respect to connecting multiple indoor units to at least one satellite antenna via a local area network with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Davis '055 would have been the application of known techniques (*e.g.*, connecting multiple indoor units to at least one satellite antenna via a local area network) to known products/systems to yield predictable results.
Davis '730	• James and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results. • James and Davis '830 would be obvious to combine because both share a common assignee.

Reference to Combine	Exemplary Motivation(s) to Combine with James
Ellis	• James and Ellis relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Ellis would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ellis with respect to the interactive television program guide system with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Ellis would have been the application of known techniques (*e.g.*, interactive television program guide system) to known products/systems to yield predictable results.
Gregoire	• James and Gregoire relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Gregoire would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gregoire with respect to distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Gregoire would have been the application of known techniques (*e.g.*, distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested

Reference to Combine	Exemplary Motivation(s) to Combine with James
	transponders on a composite signal) to known products/systems to yield predictable results.
Inose	• James and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
Kang	• James and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and

Reference to Combine	Exemplary Motivation(s) to Combine with James
	transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.
Lovinggood	• James and Lovinggood relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Lovinggood would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Lovinggood with respect to digital processing of received transponder signals with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Lovinggood would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Mutzig	• James and Mutzig relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Mutzig would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Mutzig with respect to the simultaneous reception of multiple TV channels retransmitted by satellites with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Mutzig would have been the application of known techniques (*e.g.*, simultaneous

Reference to Combine	Exemplary Motivation(s) to Combine with James
	reception of multiple TV channels retransmitted by satellites) to known products/systems to yield predictable results.
Petruzzelli	• James and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Pugel '200	• James and Pugel '200 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Pugel '200 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Pugel '200 with respect to digital processing of received transponder signals with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Pugel '200 would have been the application of known techniques (*e.g.*, digital processing of

Reference to Combine	Exemplary Motivation(s) to Combine with James
	received transponder signals) to known products/systems to yield predictable results.
Williams '419	• James and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results. • James and Williams '419 would be obvious to combine because both share a common assignee.
Williams '873	• James and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable.

Reference to Combine	Exemplary Motivation(s) to Combine with James
	• Combining James and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results. • James and Williams '873 would be obvious to combine because both share a common assignee.
Gurantz	• James and Gurantz relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Gurantz would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gurantz with respect to splitting the signal for delivery to multiple set-top boxes with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Gurantz would have been the application of known techniques (*e.g.*, splitting the signal for delivery to multiple set-top boxes) to known products/systems to yield predictable results.
Chanteau	• James and Chanteau relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Chanteau would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Chanteau with respect to broadcasting digital data channels with James's

Reference to Combine	Exemplary Motivation(s) to Combine with James
	system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Chanteau would have been the application of known techniques (*e.g.*, broadcasting digital data channels) to known products/systems to yield predictable results.
Levy	• James and Levy relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of James and Levy would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Levy with respect to converting digital signals to analog signals with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Levy would have been the application of known techniques (*e.g.*, converting digital signals to analog signals) to known products/systems to yield predictable results.
Sage	• James and Sage relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of James and Sage would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Sage with respect to combining digital signals with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Sage would have been the application of known techniques (*e.g.*, combining digital signals) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with James
Oishi	• James and Oishi relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Oishi would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Oishi with respect to the frequency conversion table with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Oishi would have been the application of known techniques (*e.g.*, the frequency conversion table) to known products/systems to yield predictable results.
Eck	• James and Eck relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Eck would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Eck with respect to storing a translation table with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Eck would have been the application of known techniques (*e.g.*, storing a translation table) to known products/systems to yield predictable results.
Freeman	• James and Freeman relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with James
	• The combination of James and Freeman would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Freeman with respect to transmitting and combining digital signals with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Freeman would have been the application of known techniques (*e.g.*, transmitting and combining digital signals) to known products/systems to yield predictable results.
Ishizaki	• James and Ishizaki relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of James and Ishizaki would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ishizaki with respect to distributing multiplexed signals to subscribers on the same physical channel with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Ishizaki would have been the application of known techniques (*e.g.*, distributing multiplexed signals to subscribers on the same physical channel) to known products/systems to yield predictable results.
Ogami	• James and Ogami relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with James
	• The combination of James and Ogami would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ogami with respect to distributing a signal received by an antenna to multiple rooms via a coaxial cable with James's system for receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable. • Combining James and Ogami would have been the application of known techniques (*e.g.*, distributing a signal received by an antenna to multiple rooms via a coaxial cable) to known products/systems to yield predictable results.

i. Combinations Based on Kang

To the extent Kang does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine Kang with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
Ardemagni	• Kang and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable.

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	• Combining Kang and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Basawapatna	• Kang and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
Behrens	• Kang and Behrens relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Behrens would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Behrens with respect to digital processing of RF signals with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Behrens would have been the application of known techniques (*e.g.*, digital processing of

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	RF signals) to known products/systems to yield predictable results.
Carnero	• Kang and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals) to known products/systems to yield predictable results.
Davis '055	• Kang and Davis '055 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with respect to connecting multiple indoor units to at least one satellite antenna via a local area network with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable.

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	• Combining Kang and Davis '055 would have been the application of known techniques (*e.g.*, connecting multiple indoor units to at least one satellite antenna via a local area network) to known products/systems to yield predictable results.
Davis '730	• Kang and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results.
Ellis	• Kang and Ellis relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Ellis would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ellis with respect to the interactive television program guide system with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable.

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	• Combining Kang and Ellis would have been the application of known techniques (*e.g.*, interactive television program guide system) to known products/systems to yield predictable results.
Gregoire	• Kang and Gregoire relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Gregoire would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gregoire with respect to distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Gregoire would have been the application of known techniques (*e.g.*, distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal) to known products/systems to yield predictable results.
Inose	• Kang and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Kang's system for

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
James	• Kang and James relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.
Lovinggood	• Kang and Lovinggood relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Lovinggood would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Lovinggood

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	with respect to digital processing of received transponder signals with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Lovinggood would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Mutzig	• Kang and Mutzig relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Mutzig would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Mutzig with respect to the simultaneous reception of multiple TV channels retransmitted by satellites with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Mutzig would have been the application of known techniques (*e.g.*, simultaneous reception of multiple TV channels retransmitted by satellites) to known products/systems to yield predictable results.
Petruzzelli	• Kang and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Pugel '200	• Kang and Pugel '200 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Pugel '200 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Pugel '200 with respect to digital processing of received transponder signals with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Pugel '200 would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Williams '419	• Kang and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Williams '873	• Kang and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Gurantz	• Kang and Gurantz relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Gurantz would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gurantz with respect to splitting the signal for delivery to multiple set-top boxes with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Gurantz would have been the application of known techniques (*e.g.*, splitting the signal for delivery to multiple set-top boxes) to known products/systems to yield predictable results.
Chanteau	• Kang and Chanteau relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Chanteau would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Chanteau with respect to broadcasting digital data channels with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Chanteau would have been the application of known techniques (*e.g.*, broadcasting digital data channels) to known products/systems to yield predictable results.
Levy	• Kang and Levy relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Kang and Levy would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Levy with respect to converting

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	digital signals to analog signals with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Levy would have been the application of known techniques (*e.g.*, converting digital signals to analog signals) to known products/systems to yield predictable results.
Sage	• Kang and Sage relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Kang and Sage would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Sage with respect to combining digital signals with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Sage would have been the application of known techniques (*e.g.*, combining digital signals) to known products/systems to yield predictable results.
Oishi	• Kang and Oishi relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Oishi would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Oishi with respect to frequency-shifting the signals to a vacant frequency band with Kang's system for receiving and distributing satellite

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Oishi would have been the application of known techniques (*e.g.*, frequency-shifting the signals to a vacant frequency band) to known products/systems to yield predictable results.
Eck	• Kang and Eck relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Eck would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Eck with respect to storing a translation table with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Eck would have been the application of known techniques (*e.g.*, storing a translation table) to known products/systems to yield predictable results.
Freeman	• Kang and Freeman relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Freeman would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Freeman with respect to transmitting and combining digital signals with Kang's system for receiving and distributing satellite broadcasting

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Freeman would have been the application of known techniques (*e.g.*, transmitting and combining digital signals) to known products/systems to yield predictable results.
Ishizaki	• Kang and Ishizaki relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Ishizaki would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ishizaki with respect to distributing multiplexed signals to subscribers on the same physical channel with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Ishizaki would have been the application of known techniques (*e.g.*, distributing multiplexed signals to subscribers on the same physical channel) to known products/systems to yield predictable results.
Ogami	• Kang and Ogami relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Kang and Ogami would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ogami with respect to distributing a signal received by an antenna to multiple

Reference to Combine	Exemplary Motivation(s) to Combine with Kang
	rooms via a coaxial cable with Kang's system for receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable. • Combining Kang and Ogami would have been the application of known techniques (*e.g.*, distributing a signal received by an antenna to multiple rooms via a coaxial cable) to known products/systems to yield predictable results.

j. Combinations Based on Lovinggood

To the extent Lovinggood does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine Lovinggood with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Lovinggood
Ardemagni	• Lovinggood and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Lovinggood and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Lovinggood's system for digital processing of received transponder signals. • Combining Lovinggood and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Basawapatna	• Lovinggood and Basawapatna relate to the same and/or related field because both relate to distributing broadband

Reference to Combine	Exemplary Motivation(s) to Combine with Lovinggood
	signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Lovinggood and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Lovinggood's system for digital processing of received transponder signals. • Combining Lovinggood and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
Behrens	• Behrens and Lovinggood relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Converting the selected signal to analog prior to combining would have been obvious in view of Lovinggood and Behrens and would have yielded predictable and desirable results of ensuring compatibility with existing components in satellite television systems, such as integrated receiver decoders. • Combining the disclosures of Lovinggood and Behrens would have been a logical extension of the existing and described signal processing techniques. • Combining Lovinggood and Behrens would have been the application of known techniques to similar products/systems.
Carnero	• Carnero and Lovinggood relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Selecting and extracting selected transponder signals after digitizing the plurality of satellite broadband signals in the ODU would have been obvious in view of Carnero and Lovinggood and would have yielded predictable and desirable results of reducing the number of components

Reference to Combine	Exemplary Motivation(s) to Combine with Lovinggood
	necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Lovinggood and Carnero would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Carnero's system for distributing television satellite signals in a community antenna system, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, with Lovinggood's digital processing of received transponder signals to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Lovinggood and Carnero would have been the application of known techniques to similar products/systems.
Chanteau	• Chanteau and Lovinggood relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Combining the disclosures of Lovinggood and Chanteau would have been a logical extension of the existing and described signal processing techniques. • Combining Lovinggood and Chanteau would have been the application of known techniques to similar products/systems.
Davis '055	• Lovinggood and Davis '055 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Lovinggood and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with respect to connecting multiple indoor units to at least one

Reference to Combine	Exemplary Motivation(s) to Combine with Lovinggood
	satellite antenna via a local area network with Lovinggood's system for digital processing of received transponder signals. • Combining Lovinggood and Davis '055 would have been the application of known techniques (*e.g.*, connecting multiple indoor units to at least one satellite antenna via a local area network) to known products/systems to yield predictable results.
Davis '730	• Lovinggood and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Lovinggood and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Lovinggood's system for digital processing of received transponder signals. • Combining Lovinggood and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results.
Ellis	• Ellis and Lovinggood relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Combining the disclosures of Lovinggood and Ellis would have been a logical extension of the existing and described satellite signal distribution techniques. • Combining Lovinggood and Ellis would have been the application of known techniques to similar products/systems.
Gregoire	• Gregoire and Lovinggood relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems.

Reference to Combine	Exemplary Motivation(s) to Combine with Lovinggood
	• Selecting and extracting selected transponder signals after digitizing the plurality of satellite broadband signals in the ODU would have been obvious in view of Lovinggood and Gregoire and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Lovinggood and Gregoire would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Gregoire's system for distribution of direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, with Lovinggood's digital processing of received transponder signals, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Lovinggood and Carnero would have been the application of known techniques to similar products/systems.
Inose	• Lovinggood and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Lovinggood and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Lovinggood's system for digital processing of received transponder signals. • Combining Lovinggood and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals with James's system for receiving

Reference to Combine	Exemplary Motivation(s) to Combine with Lovinggood
	broadband signals) to known products/systems to yield predictable results.
James	• Lovinggood and James relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Lovinggood and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Lovinggood's system for digital processing of received transponder signals. • Combining Lovinggood and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.
Kang	• Lovinggood and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Lovinggood and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Lovinggood's system for digital processing of received transponder signals. • Combining Lovinggood and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single

Reference to Combine	Exemplary Motivation(s) to Combine with Lovinggood
	cable) to known products/systems to yield predictable results.
Mutzig	• Mutzig and Lovinggood relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Selecting and extracting selected transponder signals after digitizing the plurality of satellite broadband signals in the ODU would have been obvious in view of Lovinggood and Mutzig and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Lovinggood and Mutzig would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, with Lovinggood's digital processing of received transponder signals, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Lovinggood and Mutzig would have been the application of known techniques to similar products/systems.
Petruzzelli	• Lovinggood and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Lovinggood and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted

Reference to Combine	Exemplary Motivation(s) to Combine with Lovinggood
	by a single cable with Lovinggood's system for digital processing of received transponder signals. • Combining Lovinggood and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Pugel '200	• Lovinggood and Pugel '200 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Lovinggood and Pugel '200 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Pugel '200 with respect to digital processing of received transponder signals with Lovinggood's system for digital processing of received transponder signals. • Combining Lovinggood and Pugel '200 would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Oishi	• Oishi and Lovinggood relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Combining the disclosures of Lovinggood and Oishi would have been a logical extension of the existing and described satellite signal distribution techniques. • Combining Lovinggood and Oishi would have been the application of known techniques to similar products/systems.
Williams '419	• Lovinggood and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Lovinggood
	• The combination of Lovinggood and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with Lovinggood's system for digital processing of received transponder signals. • Combining Lovinggood and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Williams '873	• Lovinggood and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Lovinggood and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Lovinggood's system for digital processing of received transponder signals. • Combining Lovinggood and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.

k. Combinations Based on Mutzig

To the extent Mutzig does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine Mutzig with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Mutzig
Ardemagni	• Mutzig and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Mutzig and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites. • Combining Mutzig and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Basawapatna	• Mutzig and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Mutzig and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites. • Combining Mutzig and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
Behrens	• Behrens and Mutzig relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems.

Reference to Combine	Exemplary Motivation(s) to Combine with Mutzig
	• Processing selected transponder signals in the digital domain and converting the selected signal back to analog prior to combining would have been obvious in view of Mutzig and Behrens and would have yielded predictable and desirable results of realizing resource-efficient digital processing while ensuring the signal would be compatible with existing components in satellite television systems, such as integrated receiver decoders. • Combining the disclosures of Mutzig and Behrens would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Behrens's digital processing of RF signals with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites to more efficiently provide those channels to a plurality of users requesting various transponder signals. • Combining Mutzig and Behrens would have been the application of known techniques to similar products/systems.
Carnero	• Mutzig and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Mutzig and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites. • Combining Mutzig and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality

Reference to Combine	Exemplary Motivation(s) to Combine with Mutzig
	of users requesting various transponder signals) to known products/systems to yield predictable results.
Chanteau	• Chanteau and Mutzig relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building). • Combining the disclosures of Mutzig and Chanteau would have been a logical extension of the existing and described signal processing techniques. • Combining Mutzig and Chanteau would have been the application of known techniques to similar products/systems.
Davis '055	• Mutzig and Davis '055 relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Digitizing the plurality of satellite broadband signals in the ODU prior to selecting and extracting selected transponder signals would have been obvious in view of Davis '055 and Mutzig and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Davis '055 and Mutzig would have been a logical extension of the existing and described satellite signal distribution and signal processing techniques, including wireless communication between IRDs and an ODU. • Additionally, a POSITA would have been motivated to combine Davis '055's digital processing of received transponder signals with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Mutzig
	• Combining Davis '055 and Mutzig would have been the application of known techniques to similar products/systems.
Davis '730	• Mutzig and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Mutzig and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites. • Combining Mutzig and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results.
Ellis	• Ellis and Mutzig relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Maintaining a channel translation table at the ODU, the channel translation table specifying assigned frequency slots for transponder signals in the composite signal, and providing the channel translation table to IRDs would have been obvious in view of Mutzig and Ellis and would have yielded predictable and desirable results of facilitating user selection of and access to satellite television channels. • Combining the disclosures of Mutzig and Ellis would have been a logical extension of the existing and described satellite signal distribution techniques. • Additionally, a POSITA would have been motivated to combine Ellis's interactive television program guide system with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites to more efficiently

Reference to Combine	Exemplary Motivation(s) to Combine with Mutzig
	provide satellite television services to facilitate user selection of and access to satellite television channels. • Combining Mutzig and Ellis would have been the application of known techniques to similar products/systems.
Gregoire	• Gregoire and Mutzig relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels. • Combining the disclosures of Gregoire and Mutzig would have been a logical extension of the existing and described satellite signal distribution and signal processing techniques, including wireless communication between IRDs and an ODU. • Combining Gregoire and Mutzig would have been the application of known techniques to similar products/systems.
Inose	• Mutzig and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Mutzig and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites. • Combining Mutzig and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
James	• Mutzig and James relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with Mutzig
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Mutzig and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites. • Combining Mutzig and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.
Kang	• Mutzig and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Mutzig and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites. • Combining Mutzig and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Mutzig
Lovinggood	• Mutzig and Lovinggood relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Digitizing the plurality of satellite broadband signals in the ODU prior to selecting and extracting selected transponder signals would have been obvious in view of Lovinggood and Mutzig and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Converting the selected signal back to analog prior to combining would have been obvious in view of Mutzig and Lovinggood and would have yielded predictable and desirable results of realizing resource-efficient digital processing while ensuring the signal would be compatible with existing components in satellite television systems, such as integrated receiver decoders. • Combining the disclosures of Lovinggood and Mutzig would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Lovinggood's digital processing of received transponder signals with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Lovinggood and Mutzig would have been the application of known techniques to similar products/systems.
Oishi	• Oishi and Mutzig relate to the same and/or related field because both relate to distributing satellite television signals at a customer/user premises (e.g., a home or office building), including where a plurality of customer/users are selecting a plurality of different channels.

Reference to Combine	Exemplary Motivation(s) to Combine with Mutzig
	• Maintaining a channel translation table at the ODU, the channel translation table specifying assigned frequency slots for transponder signals in the composite signal, and providing the channel translation table to IRDs would have been obvious in view of Mutzig and Oishi and would have yielded predictable and desirable results of facilitating user selection of and access to satellite television channels. • Combining the disclosures of Mutzig and Oishi would have been a logical extension of the existing and described satellite signal distribution techniques. • Additionally, a POSITA would have been motivated to combine Oishi's television signal distributor and receiver apparatuses (including frequency conversion table) with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites to more efficiently provide satellite television services to facilitate user selection of and access to satellite television channels. • Combining Mutzig and Oishi would have been the application of known techniques to similar products/systems.
Petruzzelli	• Mutzig and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Mutzig and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites. • Combining Mutzig and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Pugel '200	• Mutzig and Pugel '200 relate to the same and/or related field because both relate to distributing satellite transponder

Reference to Combine	Exemplary Motivation(s) to Combine with Mutzig
	channel signals at a customer/user premises (e.g., a home or office building). • Digitizing the plurality of satellite broadband signals in the ODU prior to selecting and extracting selected transponder signals would have been obvious in view of Pugel '200 and Mutzig and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Pugel '200 and Mutzig would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Pugel '200's digital processing of received transponder signals with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Pugel '200 and Mutzig would have been the application of known techniques to similar products/systems.
Williams '419	• Mutzig and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Mutzig and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites.

Reference to Combine	Exemplary Motivation(s) to Combine with Mutzig
	• Combining Mutzig and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Williams '873	• Mutzig and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Mutzig and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites. • Combining Mutzig and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.

l. Combinations Based on Petruzzelli

To the extent Petruzzelli does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine Petruzzelli with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
Ardemagni	• Petruzzelli and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Ardemagni would have yielded predictable and desirable results of receiving,

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Basawapatna	• Petruzzelli and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
Behrens	• Petruzzelli and Behrens relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Behrens would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Behrens with

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	respect to digital processing of RF signals with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Behrens would have been the application of known techniques (*e.g.*, digital processing of RF signals) to known products/systems to yield predictable results.
Carnero	• Petruzzelli and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals) to known products/systems to yield predictable results.
Davis '055	• Petruzzelli and Davis '055 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	respect to connecting multiple indoor units to at least one satellite antenna via a local area network with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Davis '055 would have been the application of known techniques (*e.g.*, connecting multiple indoor units to at least one satellite antenna via a local area network) to known products/systems to yield predictable results.
Davis '730	• Petruzzelli and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results.
Ellis	• Petruzzelli and Ellis relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Ellis would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ellis with respect to the interactive television program guide system with

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Ellis would have been the application of known techniques (*e.g.*, interactive television program guide system) to known products/systems to yield predictable results.
Gregoire	• Petruzzelli and Gregoire relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Gregoire would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gregoire with respect to distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Gregoire would have been the application of known techniques (*e.g.*, distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal) to known products/systems to yield predictable results.
Inose	• Petruzzelli and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
James	• Petruzzelli and James relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.
Kang	• Petruzzelli and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.
Lovinggood	• Petruzzelli and Lovinggood relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Lovinggood would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Lovinggood with respect to digital processing of received transponder signals with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Lovinggood would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Mutzig	• Petruzzelli and Mutzig relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Mutzig would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	been motivated to combine the disclosure of Mutzig with respect to the simultaneous reception of multiple TV channels retransmitted by satellites with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Mutzig would have been the application of known techniques (*e.g.*, simultaneous reception of multiple TV channels retransmitted by satellites) to known products/systems to yield predictable results.
Pugel '200	• Petruzzelli and Pugel '200 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Pugel '200 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Pugel '200 with respect to digital processing of received transponder signals with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Pugel '200 would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Williams '419	• Petruzzelli and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	with respect to distributing broadband signals to multiple receiver units with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Williams '873	• Petruzzelli and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Gurantz	• Petruzzelli and Gurantz relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Gurantz would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gurantz with respect to splitting the signal for delivery to multiple set-top

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	boxes with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Gurantz would have been the application of known techniques (*e.g.*, splitting the signal for delivery to multiple set-top boxes) to known products/systems to yield predictable results.
Chanteau	• Petruzzelli and Chanteau relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Chanteau would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Chanteau with respect to broadcasting digital data channels with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Chanteau would have been the application of known techniques (*e.g.*, broadcasting digital data channels) to known products/systems to yield predictable results.
Levy	• Petruzzelli and Levy relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Petruzzelli and Levy would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Levy with respect to converting digital signals to analog signals with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Levy would have been the application of known techniques (*e.g.*, converting digital

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	signals to analog signals) to known products/systems to yield predictable results.
Sage	• Petruzzelli and Sage relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Petruzzelli and Sage would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Sage with respect to combining digital signals with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Sage would have been the application of known techniques (*e.g.*, combining digital signals) to known products/systems to yield predictable results.
Oishi	• Petruzzelli and Oishi relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Oishi would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Oishi with respect to the frequency conversion table with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Oishi would have been the application of known techniques (*e.g.*, the frequency conversion table) to known products/systems to yield predictable results.
Eck	• Petruzzelli and Eck relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Eck would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Eck with respect to storing a translation table with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Eck would have been the application of known techniques (*e.g.*, storing a translation table) to known products/systems to yield predictable results.
Freeman	• Petruzzelli and Freeman relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Freeman would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Freeman with respect to transmitting and combining digital signals with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Freeman would have been the application of known techniques (*e.g.*, transmitting and combining digital signals) to known products/systems to yield predictable results.
Ishizaki	• Petruzzelli and Ishizaki relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Petruzzelli
	• The combination of Petruzzelli and Ishizaki would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ishizaki with respect to distributing multiplexed signals to subscribers on the same physical channel with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Ishizaki would have been the application of known techniques (*e.g.*, distributing multiplexed signals to subscribers on the same physical channel) to known products/systems to yield predictable results.
Ogami	• Petruzzelli and Ogami relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Petruzzelli and Ogami would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ogami with respect to distributing a signal received by an antenna to multiple rooms via a coaxial cable with Petruzzelli's system for combining signals from the ODU to be transmitted by a single cable. • Combining Petruzzelli and Ogami would have been the application of known techniques (*e.g.*, distributing a signal received by an antenna to multiple rooms via a coaxial cable) to known products/systems to yield predictable results.

m. Combinations Based on Pugel '200

To the extent Pugel '200 does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated

to combine Pugel '200 with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Pugel '200
Ardemagni	• Pugel '200 and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Pugel '200 and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Pugel '200's system for digital processing of received transponder signals. • Combining Pugel '200 and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Basawapatna	• Pugel '200 and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Pugel '200 and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Pugel '200's system for digital processing of received transponder signals. • Combining Pugel '200 and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Pugel '200
Behrens	• Behrens and Pugel '200 relate to the same and/or related field because both relate to signal processing, and specifically both disclose RF communication systems. • Converting the selected signal to analog prior to combining would have been obvious in view of Pugel '200 and Behrens and would have yielded predictable and desirable results of ensuring compatibility with existing components in satellite television systems, such as integrated receiver decoders. • Combining the disclosures of Pugel '200 and Behrens would have been a logical extension of the existing and described signal processing techniques. • Combining Pugel '200 and Behrens would have been the application of known techniques to similar products/systems.
Carnero	• Carnero and Pugel '200 relate to the same and/or related field because both relate to distributing satellite transponder channel signals at a customer/user premises (e.g., a home or office building). • Selecting and extracting selected transponder signals after digitizing the plurality of satellite broadband signals in the ODU would have been obvious in view of Pugel '200 and Carnero and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Pugel '200 and Carnero would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Carnero's system for distributing television satellite signals in a community antenna system, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, with Pugel '200's digital processing of received transponder signals to more efficiently provide satellite television services to a plurality of users requesting various transponder signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Pugel '200
	• Combining Pugel '200 and Carnero would have been the application of known techniques to similar products/systems.
Chanteau	• Chanteau and Pugel '200 relate to the same and/or related field because both relate to distributing satellite transponder channel signals at a customer/user premises (e.g., a home or office building). • Combining the disclosures of Pugel '200 and Chanteau would have been a logical extension of the existing and described signal processing techniques. • Combining Pugel '200 and Chanteau would have been the application of known techniques to similar products/systems.
Davis '055	• Pugel '200 and Davis '055 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Pugel '200 and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with respect to connecting multiple indoor units to at least one satellite antenna via a local area network with Pugel '200's system for digital processing of received transponder signals. • Combining Pugel '200 and Davis '055 would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
Davis '730	• Pugel '200 and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Pugel '200 and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have

Reference to Combine	Exemplary Motivation(s) to Combine with Pugel '200
	been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Pugel '200's system for digital processing of received transponder signals. • Combining Pugel '200 and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results.
Ellis	• Ellis and Mutzig relate to the same and/or related field because both relate to distributing satellite transponder channel signals at a customer/user premises (e.g., a home or office building). • Maintaining a channel translation table at the ODU, the channel translation table specifying assigned frequency slots for transponder signals in the composite signal, and providing the channel translation table to IRDs would have been obvious in view of Pugel '200 and Ellis and would have yielded predictable and desirable results of facilitating user selection of and access to satellite television channels. • Combining the disclosures of Pugel '200 and Ellis would have been a logical extension of the existing and described satellite signal distribution techniques. • Additionally, a POSITA would have been motivated to combine Ellis's interactive television program guide system with Pugel '200's method and apparatus for simultaneously processing carrier signals (including in satellite communications systems) to more efficiently provide satellite services to facilitate user selection of and access to satellite services. • Combining Pugel '200 and Ellis would have been the application of known techniques to similar products/systems.
Gregoire	• Gregoire and Pugel '200 relate to the same and/or related field because both relate to distributing satellite transponder channel signals at a customer/user premises (e.g., a home or office building). • Selecting and extracting selected transponder signals after digitizing the plurality of satellite broadband signals in the

Reference to Combine	Exemplary Motivation(s) to Combine with Pugel '200
	ODU would have been obvious in view of Pugel '200 and Gregoire and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Pugel '200 and Gregoire would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Gregoire's system for distribution of direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, with Pugel '200's digital processing of received transponder signals, to more efficiently provide satellite television services to a plurality of users requesting various transponder signals. • Combining Pugel '200 and Gregoire would have been the application of known techniques to similar products/systems.
Inose	• Pugel '200 and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Pugel '200 and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Pugel '200's system for digital processing of received transponder signals. • Combining Pugel '200 and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results.
James	• Pugel '200 and James relate to the same and/or related field because both relate to distributing broadband signals. Both

Reference to Combine	Exemplary Motivation(s) to Combine with Pugel '200
	references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Pugel '200 and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Pugel '200's system for digital processing of received transponder signals. • Combining Pugel '200 and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.
Kang	• Pugel '200 and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Pugel '200 and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Pugel '200's system for digital processing of received transponder signals. • Combining Pugel '200 and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.
Lovinggood	• Pugel '200 and Lovinggood relate to the same and/or related field because both relate to distributing broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Pugel '200
	Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Pugel '200 and Lovinggood would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Lovinggood with respect to digital processing of received transponder signals with Pugel '200's system for digital processing of received transponder signals. • Combining Pugel '200 and Lovinggood would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Mutzig	• Mutzig and Pugel '200 relate to the same and/or related field because both relate to distributing satellite transponder channel signals at a customer/user premises (e.g., a home or office building). • Selecting and extracting selected transponder signals after digitizing the plurality of satellite broadband signals in the ODU would have been obvious in view of Pugel '200 and Mutzig and would have yielded predictable and desirable results of reducing the number of components necessary to select and extract transponder signals and providing flexibility to increase or decrease the number of transponder signals provided to IRDs. • Combining the disclosures of Pugel '200 and Mutzig would have been a logical extension of the existing and described signal processing techniques. • Additionally, a POSITA would have been motivated to combine Mutzig's system for simultaneous reception of multiple TV channels retransmitted by satellites, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal, with Pugel '200's digital processing of received transponder signals, to more efficiently provide satellite television

Reference to Combine	Exemplary Motivation(s) to Combine with Pugel '200
	services to a plurality of users requesting various transponder signals. • Combining Pugel '200 and Mutzig would have been the application of known techniques to similar products/systems.
Oishi	• Oishi and Mutzig relate to the same and/or related field because both relate to distributing satellite transponder channel signals at a customer/user premises (e.g., a home or office building). • Maintaining a channel translation table at the ODU, the channel translation table specifying assigned frequency slots for transponder signals in the composite signal, and providing the channel translation table to IRDs would have been obvious in view of Pugel '200 and Oishi and would have yielded predictable and desirable results of facilitating user selection of and access to satellite television channels. • Combining the disclosures of Pugel '200 and Oishi would have been a logical extension of the existing and described satellite signal distribution techniques. • Additionally, a POSITA would have been motivated to combine Oishi's television signal distributor and receiver apparatuses (including frequency conversion table) with Pugel '200's method and apparatus for simultaneously processing carrier signals (including in satellite communications systems) to more efficiently provide satellite services to facilitate user selection of and access to satellite services. • Combining Pugel '200 and Oishi would have been the application of known techniques to similar products/systems.
Petruzzelli	• Pugel '200 and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Pugel '200 and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have

Reference to Combine	Exemplary Motivation(s) to Combine with Pugel '200
	been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with Pugel '200's system for digital processing of received transponder signals. • Combining Pugel '200 and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Williams '419	• Pugel '200 and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Pugel '200 and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with Pugel '200's system for digital processing of received transponder signals. • Combining Pugel '200 and Williams '419 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.
Williams '873	• Pugel '200 and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Pugel '200 and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Pugel '200's system for digital processing of received transponder signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Pugel '200
	• Combining Pugel '200 and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results.

n. Combinations Based on Williams '419

To the extent Williams '419 does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine Williams '419 with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
Ardemagni	• Williams '419 and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Basawapatna	• Williams '419 and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals,

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
	including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
Behrens	• Williams '419 and Behrens relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Behrens would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Behrens with respect to digital processing of RF signals with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Behrens would have been the application of known techniques (*e.g.*, digital processing of RF signals) to known products/systems to yield predictable results.
Carnero	• Williams '419 and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
	satellite television services to a plurality of users requesting various transponder signals with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals) to known products/systems to yield predictable results.
Davis '055	• Williams '419 and Davis '055 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with respect to connecting multiple indoor units to at least one satellite antenna via a local area network with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Davis '055 would have been the application of known techniques (*e.g.*, connecting multiple indoor units to at least one satellite antenna via a local area network) to known products/systems to yield predictable results. • Williams '419 and Davis '055 share a common original assignee.
Davis '730	• Williams '419 and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
	over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results. • Williams '419 and Davis '730 share a common original assignee.
Ellis	• Williams '419 and Ellis relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Ellis would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ellis with respect to the interactive television program guide system with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Ellis would have been the application of known techniques (*e.g.*, interactive television program guide system) to known products/systems to yield predictable results.
Gregoire	• Williams '419 and Gregoire relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Gregoire would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
	over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gregoire with respect to distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Gregoire would have been the application of known techniques (*e.g.*, distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal) to known products/systems to yield predictable results. • Gregoire explains that its "disclosure will focus the invention's application on the" Hughes DTV system, and Williams '419 was originally assigned to Hughes.
Inose	• Williams '419 and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
James	• Williams '419 and James relate to the same and/or related field because both relate to distributing broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
	Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.
Kang	• Williams '419 and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
	cable) to known products/systems to yield predictable results.
Lovinggood	• Williams '419 and Lovinggood relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Lovinggood would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Lovinggood with respect to digital processing of received transponder signals with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Lovinggood would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Mutzig	• Williams '419 and Mutzig relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Mutzig would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Mutzig with respect to the simultaneous reception of multiple TV channels retransmitted by satellites with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Mutzig would have been the application of known techniques (*e.g.*, simultaneous

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
	reception of multiple TV channels retransmitted by satellites) to known products/systems to yield predictable results.
Petruzzelli	• Williams '419 and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Pugel '200	• Williams '419 and Pugel '200 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Pugel '200 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Pugel '200 with respect to digital processing of received transponder signals with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Pugel '200 would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
Williams '873	• Williams '419 and Williams '873 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Williams '873 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '873 with respect to distributing broadband signals to multiple receiver units with Williams '419's system for the same. • Combining Williams '419 and Williams '873 would have been the application of known techniques (*e.g.*, distributing broadband signals to multiple receiver units) to known products/systems to yield predictable results. • Williams '873 and Williams '419 share a common inventor and original assignee.
Gurantz	• Williams '419 and Gurantz relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Gurantz would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gurantz with respect to splitting the signal for delivery to multiple set-top boxes with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Gurantz would have been the application of known techniques (*e.g.*, splitting the signal for delivery to multiple set-top boxes) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
Chanteau	• Williams '419 and Chanteau relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Chanteau would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Chanteau with respect to broadcasting digital data channels with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Chanteau would have been the application of known techniques (*e.g.*, broadcasting digital data channels) to known products/systems to yield predictable results.
Levy	• Williams '419 and Levy relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Williams '419 and Levy would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Levy with respect to converting digital signals to analog signals with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Levy would have been the application of known techniques (*e.g.*, converting digital signals to analog signals) to known products/systems to yield predictable results.
Sage	• Williams '419 and Sage relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
	• The combination of Williams '419 and Sage would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Sage with respect to combining digital signals with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Sage would have been the application of known techniques (*e.g.*, combining digital signals) to known products/systems to yield predictable results.
Oishi	• Williams '419 and Oishi relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Oishi would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Oishi with respect to the frequency conversion table with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Oishi would have been the application of known techniques (*e.g.*, the frequency conversion table) to known products/systems to yield predictable results.
Eck	• Williams '419 and Eck relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Eck would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
	been motivated to combine the disclosure of Eck with respect to storing a translation table with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Eck would have been the application of known techniques (*e.g.*, storing a translation table) to known products/systems to yield predictable results.
Freeman	• Williams '419 and Freeman relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Freeman would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Freeman with respect to transmitting and combining digital signals with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Freeman would have been the application of known techniques (*e.g.*, transmitting and combining digital signals) to known products/systems to yield predictable results.
Ishizaki	• Williams '419 and Ishizaki relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Ishizaki would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ishizaki with respect to distributing multiplexed signals to subscribers on the same physical channel with Williams '419's system for distributing broadband signals to multiple receiver units.

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '419
	• Combining Williams '419 and Ishizaki would have been the application of known techniques (*e.g.*, distributing multiplexed signals to subscribers on the same physical channel) to known products/systems to yield predictable results.
Ogami	• Williams '419 and Ogami relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '419 and Ogami would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ogami with respect to distributing a signal received by an antenna to multiple rooms via a coaxial cable with Williams '419's system for distributing broadband signals to multiple receiver units. • Combining Williams '419 and Ogami would have been the application of known techniques (*e.g.*, distributing a signal received by an antenna to multiple rooms via a coaxial cable) to known products/systems to yield predictable results.

o. Combinations Based on Williams '873

To the extent Williams '873 does not anticipate and/or render obvious on its own any of the Asserted Claims of the '576 patent, a person of ordinary skill in the art would have been motivated to combine Williams '873 with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
Ardemagni	• Williams '873 and Ardemagni relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	• The combination of Williams '873 and Ardemagni would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ardemagni with respect to distributing television and telecommunication services with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Ardemagni would have been the application of known techniques (*e.g.*, distributing television and telecommunication services) to known products/systems to yield predictable results.
Basawapatna	• Williams '873 and Basawapatna relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Basawapatna would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Basawapatna with respect to distributing the broadband signal to a plurality of user devices with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Basawapatna would have been the application of known techniques (*e.g.*, distributing the broadband signal to a plurality of user devices) to known products/systems to yield predictable results.
Behrens	• Williams '873 and Behrens relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Behrens would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	been motivated to combine the disclosure of Behrens with respect to digital processing of RF signals with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Behrens would have been the application of known techniques (*e.g.*, digital processing of RF signals) to known products/systems to yield predictable results.
Carnero	• Williams '873 and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals) to known products/systems to yield predictable results.
Davis '055	• Williams '873 and Davis '055 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	respect to connecting multiple indoor units to at least one satellite antenna via a local area network with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Davis '055 would have been the application of known techniques (*e.g.*, connecting multiple indoor units to at least one satellite antenna via a local area network) to known products/systems to yield predictable results. • Williams '873 and Davis '055 share a common original assignee.
Davis '730	• Williams '873 and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals over a single cable line with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple satellite signals over a single cable line) to known products/systems to yield predictable results. • Williams '873 and Davis '730 share a common original assignee.
Ellis	• Williams '873 and Ellis relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Ellis would have yielded predictable and desirable results of receiving,

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ellis with respect to the interactive television program guide system with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Ellis would have been the application of known techniques (*e.g.*, interactive television program guide system) to known products/systems to yield predictable results.
Gregoire	• Williams '873 and Gregoire relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Gregoire would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gregoire with respect to distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Gregoire would have been the application of known techniques (*e.g.*, distributing direct-to-home wireless services, including selecting and extracting requested transponder signals and delivering the requested transponders on a composite signal) to known products/systems to yield predictable results. • Gregoire explains that its "disclosure will focus the invention's application on the" Hughes DTV system, and Williams '873 was originally assigned to Hughes.

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
Inose	• Williams '873 and Inose relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Inose would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Inose with respect to distributing digital broadband signals with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Inose would have been the application of known techniques (*e.g.*, distributing digital broadband signals) to known products/systems to yield predictable results.
James	• Williams '873 and James relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and James would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of James with respect to receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and James would have been the application of known techniques (*e.g.*, receiving broadband signals at an ODU and distributing it to IRDs via a single distribution cable) to known products/systems to yield predictable results.

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	• Williams '873 and James would be obvious to combine because both share a common assignee.
Kang	• Williams '873 and Kang relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Kang would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Kang with respect to receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Kang would have been the application of known techniques (*e.g.*, receiving and distributing satellite broadcasting signals through a common antenna and transmitting it to subscribers through a single cable) to known products/systems to yield predictable results.
Lovinggood	• Williams '873 and Lovinggood relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Lovinggood would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Lovinggood with respect to digital processing of received transponder signals with Williams '873's system for distributing broadband signals to multiple receiver units.

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	• Combining Williams '873 and Lovinggood would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Mutzig	• Williams '873 and Mutzig relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Mutzig would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Mutzig with respect to the simultaneous reception of multiple TV channels retransmitted by satellites with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Mutzig would have been the application of known techniques (*e.g.*, simultaneous reception of multiple TV channels retransmitted by satellites) to known products/systems to yield predictable results.
Petruzzelli	• Williams '873 and Petruzzelli relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Petruzzelli would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Petruzzelli with respect to combining signals from the ODU to be transmitted by a single cable with Williams '873's system for distributing broadband signals to multiple receiver units.

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	• Combining Williams '873 and Petruzzelli would have been the application of known techniques (*e.g.*, combining signals from the ODU to be transmitted by a single cable) to known products/systems to yield predictable results.
Pugel '200	• Williams '873 and Pugel '200 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Pugel '200 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Pugel '200 with respect to digital processing of received transponder signals with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Pugel '200 would have been the application of known techniques (*e.g.*, digital processing of received transponder signals) to known products/systems to yield predictable results.
Williams '419	• Williams '873 and Williams '419 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Williams '419 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Williams '419 with respect to distributing broadband signals to multiple receiver units with Williams '873's system for the same. • Combining Williams '873 and Williams '419 would have been the application of known techniques (*e.g.*, distributing

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	broadband signals to multiple receiver units) to known products/systems to yield predictable results. • Williams '873 and Williams '419 share a common inventor and original assignee.
Gurantz	• Williams '873 and Gurantz relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Gurantz would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Gurantz with respect to splitting the signal for delivery to multiple set-top boxes with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Gurantz would have been the application of known techniques (*e.g.*, splitting the signal for delivery to multiple set-top boxes) to known products/systems to yield predictable results.
Chanteau	• Williams '873 and Chanteau relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Chanteau would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Chanteau with respect to broadcasting digital data channels with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Chanteau would have been the application of known techniques (*e.g.*, broadcasting

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	digital data channels) to known products/systems to yield predictable results.
Levy	• Williams '873 and Levy relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Williams '873 and Levy would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Levy with respect to converting digital signals to analog signals with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Levy would have been the application of known techniques (*e.g.*, converting digital signals to analog signals) to known products/systems to yield predictable results.
Sage	• Williams '873 and Sage relate to the same and/or related field because both relate to processing signals. Both references discuss aspects of processing signals. • The combination of Williams '873 and Sage would have yielded predictable and desirable results of processing signals, including broadband signals communicated over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Sage with respect to combining digital signals with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Sage would have been the application of known techniques (*e.g.*, combining digital signals) to known products/systems to yield predictable results.
Oishi	• Williams '873 and Oishi relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals.

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	• The combination of Williams '873 and Oishi would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Oishi with respect to the frequency conversion table with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Oishi would have been the application of known techniques (*e.g.*, the frequency conversion table) to known products/systems to yield predictable results.
Eck	• Williams '873 and Eck relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Eck would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Eck with respect to storing a translation table with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Eck would have been the application of known techniques (*e.g.*, storing a translation table) to known products/systems to yield predictable results.
Freeman	• Williams '873 and Freeman relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Freeman would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	been motivated to combine the disclosure of Freeman with respect to transmitting and combining digital signals with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Freeman would have been the application of known techniques (*e.g.*, transmitting and combining digital signals) to known products/systems to yield predictable results.
Ishizaki	• Williams '873 and Ishizaki relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Ishizaki would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ishizaki with respect to distributing multiplexed signals to subscribers on the same physical channel with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Ishizaki would have been the application of known techniques (*e.g.*, distributing multiplexed signals to subscribers on the same physical channel) to known products/systems to yield predictable results.
Ogami	• Williams '873 and Ogami relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Williams '873 and Ogami would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including communicating a plurality of transponder signals over a single cable. For example, a POSITA would have been motivated to combine the disclosure of Ogami with respect to distributing a signal received by an antenna to

Reference to Combine	Exemplary Motivation(s) to Combine with Williams '873
	multiple rooms via a coaxial cable with Williams '873's system for distributing broadband signals to multiple receiver units. • Combining Williams '873 and Ogami would have been the application of known techniques (*e.g.*, distributing a signal received by an antenna to multiple rooms via a coaxial cable) to known products/systems to yield predictable results.

2. '715 Patent

a. Combinations Based on Ardemagni

To the extent Ardemagni does not anticipate and/or render obvious on its own any of the Asserted Claims of the '715 patent, a person of ordinary skill in the art would have been motivated to combine Ardemagni with the following other references, for the reasons noted in the chart below, as well as for the reasons described throughout this Section:

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
Carnero	• Ardemagni and Carnero relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Carnero would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including a plurality of transponder signals in a composite signal through, for example, a local area network. For example, a POSITA would have been motivated to combine the disclosure of Carnero with respect to distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality of users requesting various transponder signals with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Carnero would have been the application of known techniques (*e.g.*, distributing television satellite signals in a community antenna system to more efficiently provide satellite television services to a plurality

	of users requesting various transponder signals) to known products/systems to yield predictable results.
Davis '055	• Ardemagni and Davis '055 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Davis '055 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including a plurality of transponder signals in a composite signal through, for example, a local area network. For example, a POSITA would have been motivated to combine the disclosure of Davis '055 with respect to connecting multiple indoor units to at least one satellite antenna via a local area network with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Davis '055 would have been the application of known techniques (*e.g.*, connecting multiple indoor units to at least one satellite antenna via a local area network) to known products/systems to yield predictable results.
Davis '730	• Ardemagni and Davis '730 relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Davis '730 would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including a plurality of transponder signals in a composite signal through, for example, a local area network. For example, a POSITA would have been motivated to combine the disclosure of Davis '730 with respect to distributing multiple satellite signals with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Davis '730 would have been the application of known techniques (*e.g.*, distributing multiple

Reference to Combine	Exemplary Motivation(s) to Combine with Ardemagni
	satellite signals) to known products/systems to yield predictable results.
Ellis	• Ardemagni and Ellis relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Ellis would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including a plurality of transponder signals in a composite signal through, for example, a local area network. For example, a POSITA would have been motivated to combine the disclosure of Ellis with respect to the interactive television program guide system with Ardemagni's system for receiving broadband signals at an ODU and distributing it to IRDs. • Combining Ardemagni and Ellis would have been the application of known techniques (*e.g.*, interactive television program guide system) to known products/systems to yield predictable results.
Fisk	• Ardemagni and Fisk relate to the same and/or related field because both relate to distributing broadband signals. Both references discuss aspects of receiving, selecting, combining, and distributing the broadband signals. • The combination of Ardemagni and Fisk would have yielded predictable and desirable results of receiving, selecting, combining, and distributing the broadband signals, including a plurality of transponder signals in a composite signal through, for example, a local area network. For example, a POSITA would have been motivated to combine the disclosure of Fisk with respect to its system and method of distributing television, video and other signals with Ardemagni's system for distributing television and telecommunication services. • Combining Ardemagni and Fisk would have been the application of known techniques (*e.g.*, system and method of
